Abstract

The problems of the automatic compound word and discretionary hyphenation in T_EX are discussed. These hyphenation points have to be marked manually in the T_EX source file so far. Several methods how to tackle with these problems are observed. The results obtained from experiments with German word-list are discussed.

1 Motivation

... problems [with hyphenation] have more or less disappeared, and I've learnt that this is only because, nowadays, every hyphenation in the newspaper is manually checked by human proof-readers.
(Jarnefors, 1995)

In (Sojka and Ševeček, 1994) (reprinted in these Proceedings) we presented a case study of problems related to achieving quality hyphenation in T_EX—especially pattern generation for flexive languages like Czech. It was shown that pretty much issues can be handled within the frame of good old T_EX, but some of them definitely not, because T_EX wasn't primarily designed from the beginning as a universal tool for the typesetting of all kinds of publications in all languages, but typesetting of The Art of Computer Programming (Knuth, 1968–94) in American English was the initial motivation.

In this paper we continue elaborating these issues, with the emphasis on the hyphenation problems in the presence of long compound words in Germanic (and Slavic) languages.

2 Problems

2.1 Compounds. The main problem with automatic hyphenation was nicely expressed on ISO-10646 electronic discussion list by Jarnefors:

“The leading Swedish daily newspaper Dagens Nyheter had severe problems with sometimes occurring incorrect hyphenations a couple of years ago. It (and its computerised typesetting) was during a period the object of much amusement, ridicule and irritation from its readers. These problems have more or less disappeared, and I've learnt that this is

only because, nowadays, *every* hyphenation in the newspaper is manually checked by human proof-readers. Because of the higher frequency of long words in Swedish compared to e.g. English or French, around a third of all lines in a typical newspaper article (with approximately 30 characters per line) end with a hyphenated word.

The hyphenation problems in Swedish have to do with the high frequency of compound words (the Swedish vocabulary can't be enumerated: new compounds are easily created by anyone) and the rule that a compound word shall always be hyphenated between the constituent word parts, to ease the flow of reading.”

For instance, in German and Czech there are no hyphens in compound words, you take the first word, rarely a fill-char and the second word. In some languages, compounds are built with hyphens. With this construction, it is easy to break at the end of line and to spell-check. However, in most of the languages compound word boundaries cannot be deducted from syntax only.

2.2 Dependency of hyphenation points on semantics.

In some cases, even the context of the sentence is needed in order to be able to decide on the hyphenation point. Collection of examples for several languages follows:

Czech *nar/val* ‘narwhal’ and *na/rval* ‘gathered by tearing, plucked’; *pod/robit* ‘subjugate, to bring under one's domination’ and *po/drobit* ‘to crumble’; *o/blít* ‘to vomit up’ and *ob/lít* ‘to pour around’

Danish *træ/kvinden* ‘the wood lady’ and *træk/vinden* ‘the draught’; *ku/plet* ‘verse’ and *kup/let* ‘domed’

Dutch *kwart/slagen* ‘quarter turns’ and *kwarts/lagen* ‘quartz layers’; *go/spel* ‘the game of Go’ and *gos/pel* ‘certain type of music’; *rots/tempel* ‘rock temple’ and *rot/stempel* ‘damned stamp’; *d/kramp* ‘cramp in the thighs’ and *dk/ramp* ‘dike catastrophe’; *ver/ste* ‘farthest’ and *vers/te* ‘most fresh’.

English *rec/ord* and *re/cord*

German *Staub/ecken* ‘dusty eck’ and *Stau/becke* ‘traffic jam in the valley’; *Wach/stube* ‘guard room’ and *Wachs/tube* ‘wax tube’

2.3 Exceptions. Some hyphenation points are forbidden because of unwanted connotations the new parts of the word may have:

Czech *kni/hovna*, *sere/náda*, *tlu/močení*, *se/kunda*

English *the/rapists*, *anal/ysis*

German *Spargel/der*, *beste/hende*, *Gehörner/ven*, *bein/halten*, *Stiefel/tern*

2.4 Discretionary hyphenation points.

1. `\discretionary{xx}{x}{xx}` (in German, *x* is a consonant **f**, **l**, **m**, **n**, **p**, **r** or **t**)

Now there will be the situation that the first word ends with a double consonant and the second word starts with the same consonant. If the second letter of the second word is a consonant, nothing changes — *Sauerstoff* + *Flasche* composes to *Sauerstoffflasche*. If the second letter of the second word is a vowel, the three consonants will be reduced to two — *Schiff* + *Fahrt* composes to *Schiffahrt*. One can find meaning-dependent discretionaries: *Bett/tuch* ‘sheet’ vs. *Bet/tuch* ‘prayer shawl’.

2. `\discretionary{k}{k}{ck}` (German)

This discretionary (as most of the others) has the rationale in the fact that pronunciation of **c** depends on the following letter (as in other languages). If hyphen occurs just after the letter **c**, the reading is slowed down because the reader doesn’t know how to pronounce it and the eye has a long way to the beginning of the next line.

Even here the hyphenation can depend on the word meaning: word *Druckerzeugnis* is hyphenated *Druck/erzeugnis* in case of ‘printed matter’ or *Druk/kerzeugnis* when speaking about ‘certificate for a printer’.¹

¹ The German speaking countries are in the process of introducing new rules for hyphenation, in which **ck** is not any more allowed to be hyphenated. With the new rules, an old way which was introduced in 1902 — e.g. hyphenation of *Zuk/ker* ‘sugar’ might change to *Zu/cker* in the future norm.

3. `\discretionary{a}{}{aa}` (Dutch)

There is another type of discretionary in which a character is deleted in case hyphenation occurs — word *omaatje* becomes *oma/tje* when hyphenated.

4. `\discretionary{é}{}{ee}` (Dutch)

Apart from character deletion another change may occur: *cafeetje* becomes *café-tje* when hyphenated.

5. `\discretionary{l}{l}{ll}` (Catalan)

In Catalan the word parallel is broken as *paral/lel*, *intelligencia* as *intel/ligencia*. **ll** is considered as one character (trigraph). With this hyphenation it changes to another two characters.

2.5 Stability of a language. Another complication is the fact that language is not fixed, non-evolving entity, but it changes, sometimes quite rapidly. New words, especially compounds, are being adopted every day. An example of an adaptation of a language to the technology — the typewriter and telegraphy in this case — may serve different spelling allowed for unlauded characters **ä**, **ö**, **ü** and **ß** in German (ae, oe, ue, ss). Some compounds are becoming perceived as base words. Thus the idea of fixing hyphenation algorithm/patterns once and forever is not a clever one.² A solution may consist in relatively easy generation of algorithm or patterns from the updated dictionary or description of changes.

3 Solutions

3.1 Compounds. It is obvious that we need to take the burden of the manual markup of compound word borders from the writer and leave it to the machine (typesetting system). The proper solution of this problem is a language module for every language, with the ability of creating new words by composition from others. This module, based on the morphology of a language, is needed, e.g., in spellchecker for that language anyway. Most probably, such language modules will become a part of the language support of operating systems in near future. Such dynamic libraries will be shared among software applications. Building such a module, however, is not a trivial task, because only some of the compounds are meaningful words.

² When storing document for later retypesetting with T_EX we also have to save the hyphenation patterns.

Table 1: Example of discretionary hyphenation table for German

pre break	post break	no break	left	right	discretionary	example
text	text	text	context	context	character	
1	2	3	4	5	6	7
k	k	ck	c	k	c_1	Drucker
ek	k	äck	äc	k	c_2	Bäcker
ff	f	f	f	f	c_3	Schiffahrt
ll	l	l	l	l	c_4	Rolladen
mm	m	m	m	m	c_5	Programmeister
nn	n	n	n	n	c_6	Brennessel
pp	p	p	p	p	c_7	Stoppunkt
rr	r	r	r	r	c_8	Herraum
tt	t	t	t	t	c_9	Balettheater

Looking for a temporary \TeX patch that will help the current \TeX users, especially those writing in Germanic and Slavic languages, the following algorithm may be used (compare with (Sojka and Ševeček, 1994)):

1. For a particular language a special word-list is created, which contains all word forms, but only compound word borders are marked there.
2. Hyphenation patterns from this word-list are created by PATGEN (Liang and Breitenlohner, 1991).
3. Special pass in the paragraph breaking algorithm of \TeX (for detailed description consult (Knuth and Plass, 1981; Knuth, 1986a; Knuth, 1986b)) is added after the first (no hyphenation trial) pass. Words are hyphenated using the compound word patterns. Then, extra penalty `\compoundwordhyphenpenalty` is associated with these hyphenation points.
4. If `\tolerance` hasn't been met by now, further hyphenation points are added using the 'standard' patterns. These new hyphenation points have associated `\hyphenpenalty`, allowing differentiation between the two types of hyphenation points.
5. Hyphenation points 'near' the word borders (specified by `\leftdiscretionaryhyphenmin` and `\rightdiscretionaryhyphenmin` are suppressed (removed).
6. Algorithm now continues with the 'old' second and eventually the third (`\emergencystretch`) passes.
7. `\compoundwordchar` (as e.g. in Cork-coded fonts `\char'027`) is included at compound word breakpoint in order to prevent ligatures spanning over the word borders *šéflékař* 'chief

doctor' versus *šéflékař* which is wrong due to fl ligature).

3.2 Discretionary hyphenation points.

Manual insertion of discretionary points is tedious and it is usually forgotten³, leading to typographic errors.

One solution is the following one. For every language a table of possible discretionary points is created. For German example see Table 3.1.

In the word-list, the words with these discretionary points are added with the "discretionary character" inserted between "left context" and "right context". From such extended word-list the patterns are generated.

The hyphenation algorithm of \TeX (for details see (Knuth, 1986a), parts 38–43, sections 813–965) has to be extended. Roughly speaking

1. As a first step, "normal" hyphenation points in the word in question are found.
2. The discretionary exception table is looked up (similar to the `\hyphenation` list of exception). If the word is found there, discretionary is inserted and algorithm ends, otherwise continue by the step 3.
3. The discretionary table is looked up and at the hyphenation points that match "left and right context" strings (columns 4 and 5 in Table 3.1), the "discretionary character" (column 6) is inserted. Such a word is hyphenated once again to check whether this discretionary really applies at this position. If so, the corresponding discretionary (columns 1–3 of the Table 3.1) is automatically inserted.

³ How many of you, \TeX users, remember to type `eigh\discretionary{t}{t}{t}een` instead of just `eighteen`?

4. “Normal” hyphenation points, which appear ‘near’ to “discretionary” hyphenation points (within the ‘window’ specified by the values of counters `\leftdiscretionaryhyphenmin` and `\rightdiscretionaryhyphenmin`), are removed.

This approach takes the advantage of the data structure used for storing the information about the hyphenation points. The patterns are stored using the *trie* data structure (see (Knuth, 1973), pp. 481–505). This data structure allows effective prefix and postfix compression. Because of that, the increase in the size of the patterns is negligible, as the patterns doublets share both prefix and postfix parts in the trie.

Also, the look up time in the trie is linear with respect to the word length of hyphenated words. The time needed for looking up in the trie for the second time is thus acceptable—it is only performed sometimes—when the context of a hyphenation point is matched in the discretionary table.

The algorithm is backward compatible in the sense that if discretionary table is not present for the current language, nothing changes with respect to the standard \TeX behaviour.

3.3 Exceptions. The exceptions can be reasonably handled by the patterns. Although the generation of patterns for languages with lots of exceptions may lead to the complex patterns, it is much better to regenerate the patterns with the exceptions than maintaining huge lists of exceptions and to slow down the processing considerably.

Because regenerating of patterns is not always possible, to allow enrichment of the knowledge of discretionary hyphenation points compiled into the patterns, it is wise to introduce new `\discretionaryhyphenation` for this purpose.

4 Experiments

For experiments we had several databases of words available. For flexive languages (Czech, German), they were based on morphology, for English it was just a list of word forms. We did our **PATGEN** experiments with German word-list generated from the full word-list by our stratified sampling technique very similar to that we described on page 63 in (Sojka and Ševčák, 1994) for Czech. We took German because the problems there are the most serious. Simple statistics show how the languages differ:

4.1 Non-uniformity of languages. In the Table 2 on page 295 there are histograms of word lengths in our databases. Although it is clear that shorter words are more frequent than the long ones, we see that in German the average word is

much longer than in English and also in Czech. It is interesting to compare the total number of words. As Czech is very flexive language, from about 170 000 word stems we got more than 3 300 000 word forms. One can compare that with the best English dictionaries and spellers, which have not more than 200 000 word forms. Flexive number (ratio of total number of word form and number of word stems) for German is about 3 (we have about 120 000 word stems), but for Czech it is almost 20.

The average word length depends on the word-list chosen, but in general our results are commensurable with the result published for Welsh (Haralambous, 1993)—9.71 characters per word, but the words like *Llanfairpwllgwyngyllgogerychwryndrob-wlllantysiliogogoch* were not taken into account there.

4.2 Compounds (German). In the word-list, only the compound word borders and prefixes were marked. This led to about 150 000 positions in our German word-list. The words without any breaks of this kind were not removed. The results of **PATGEN** runs applied to this word-list are summarised in tables 3 and 4. The efficiency achieved (about 90% breaks covered) is pretty sufficient, as ‘normal’ hyphenation pass follows and the error when hyphenation point is classified as ‘normal’ instead of ‘compound’ reflects only different penalty associated with this break. At the expense of pattern size we can do even better (see Table 5).

4.3 Discretionary hyphenation points.

In our German word-list we had 1626 words with the *c-k* discretionary and 42 words with the discretionary hyphenation of type *x-x*, where *x* is a consonant—(see Table 3.1, (Raichle, 1995) or (DUDEN, 1991) for a list of possible discretions in German).

Then we created doublets of these words with these discretions by inserting the discretionary character (column 6) at the hyphenation position and added them to our word-list. Then we applied **PATGEN** at this new word-list. Results can be compared in tables 6 and 7. The difference in pattern size is small as expected—the size of pattern file increased by less than 0.4kB, which makes difference in the trie structure of about 100 bytes only.

5 Conclusions

We are claiming that the integration of language modules with build-in knowledge about a particular language is a must in today’s top-rated systems

for publishing. We suggested extensions of hyphenation algorithms of $\text{T}_{\text{E}}\text{X}$ that may help with hyphenation especially in Germanic languages with high frequency of compound words and discretionary hyphenation. Suggested extensions are possible with limited changes to $\text{T}_{\text{E}}\text{X}$ —The Program (Knuth, 1986a). Their implementation in any conservative successor to $\text{T}_{\text{E}}\text{X}$ will be rather straightforward and when agreed on their usefulness they will be implemented as a independent change files in the future. It remains to be decided on the extended syntax and primitives our approach needs.

6 Acknowledgement

The presentation of this work has been made possible due to the support of Czech Grant Agency (grant Nr. 201/93/1269). The author would like to thank Pavel Ševeček (LOGOS, Inc.) for providing language word-lists to make the experiments and for valuable discussions on these topics. I also thank everyone who helped to improve the wording of this paper.
