CHAPTER 9: AUTHENTICATION, SECRET SHARING and e-COMMERCE

Part IX

Identification, authentication, secret sharing and e-commerce

# CHAPTER 9: AUTHENTICATION, SECRET SHARING and e-COMMERCE

IV054 9. Identification, authentication, secret sharing and e-commerc

CONTENTS I USER IDENTIFICATION and MESSAGE	
AUTHENTICATION/INTEGRITY	

Most of today's cryptographic applications ask for identification of communicating parties, and/or for data integrity/authentication during communication, rather than for secrecy of transferring data.

#### Main related problems to deal with are:

- **User identification (authentication)**: How can a person/computer prove her/his identity?
- Message authentication: Can tools be provided to find out, for the recipient, that the message is indeed from the person who was supposed to send it?
- Message integrity (authentication): Can tools be provided to decide for the recipient whether or not the message was changed on the fly?

Important practical objectives are to find identification schemes that are so simple that they can be implemented on smart cards – they are essentially credit cards equipped with a chip that can perform arithmetical operations and communications.

MORE FORMALLY and MORE GENERALLY

- Authentication is in particular the act of conforming an identity of a communication entity (person), and in general the act of conforming the truth of an attribute of a datum or entity.
- Data integrity refers to maintaining and ensuring the accuracy and consistency of data over its entire life cycle - the accuracy, validity and correctness of data should be ensured from hardware failures, software errors and human errors.

With all of the above problems we will deal in the first part of this chapter.

3/75

prof. Jozef Gruska

CONTENTS II SECRET SHARING and E-COMMERCE	USER IDENTIFICATION (AUTHENTICATION)
<ul> <li>Secret sharing problem is the problem how to share a "secret" among a group of users in such a way that only well specified subsets of them can determine the secret.</li> <li>Secret sharing schemes are ideal, for example, for storing information that is highly sensitive and important. For example, for encryption keys.</li> <li>Secret sharing protocols/schemes are another often used cryptographic primitives, with a variety of applications, we will deal with in second part of this chapter.</li> <li>E-commerce: One of the main new applications of the cryptographic techniques is to establish secure and convenient manipulation with digital money (e-money), especially for e-commerce.</li> <li>An example how e-commerce can be realized, in a simplified setting, will be shown at the end of this chapter.</li> </ul>	<ul> <li>User identification (authentication) is a process at which one party (often referred to as a Prover or as Alice), convinces a second party (often referred to as a Verifier or as Bob) of Prover's identity.</li> <li>Namely, that the Prover (Alice) convinces the other party that she has indeed participated in the identification process.</li> <li>In other words that the Prover has been herself active in proving her identity in the time the confirmative evidence of her identity has been required.</li> <li>The purpose of any identification (authentication) process is to preclude (vylucit) some impersonation (zosobnenie) of one person (the Prover) by someone else.</li> <li>Identification usually serves to control access to a resource (often a resource should be accessed only by privileged users).</li> </ul>
prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 5/75 OBJECTIVES of IDENTIFICATIONS	prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 6/75 IDENTIFICATION SYSTEM BASED on a PKC
<ul> <li>User identification process has to satisfy the following objectives:</li> <li>The Verifier will accept Prover's identity if both parties are honest;</li> <li>The Verifier cannot later, after participating in a successful identification, learn how to act as the Prover and to identify himself (as the Prover) to another Verifier;</li> <li>A third party (called attacker here), say <i>E</i>, following the identification process of the Prover to the Verifier has only a negligible chance to identify itself to someone else successfully as the Prover;</li> <li>Each of the above conditions remains true even if an attacker has observed, or has participated in, several identification processes of the same party.</li> </ul>	<ul> <li>Alice chooses a random r and sends e<sub>B</sub>(r) to Bob.</li> <li>Alice identifies a communicating person as Bob if he can send her back r.</li> <li>Bob identifies a communicating person as Alice if she can send him back r.</li> <li>A misuse of the above system</li> <li>We show that (any non-honest) Alice could misuse the above identification scheme.</li> <li>Indeed, Alice could intercept a communication of Jane (some new "player") with Bob, and get a cryptotext e<sub>B</sub>(w), the one Jana has been sending to Bob, and then Alice could send e<sub>B</sub>(w) to Bob.</li> <li>Honest Bob, who follows fully the protocol, would then return w to Alice and she would</li> </ul>

encoding algorithm $A_k$	IDENTIFICATION SYSTEM BASED on a PKC - a better version	ELEMENTARY AUTHENTICATION PROTOCOLS
CHALLENGE-RESPONSE PROTOCOLS - A SPECIFICATIONTHREE-WAY AUTHENTICATION and also KEY-AGREEMENT IIn a challenge-response identification protocol a party A proves its identity to a party B by demonstrating knowledge of a secret/method known to be associated with A only without revealing the secret/method itself to B.In this protocol a PKC will be used with encryption/decryption algorithms $(e_U, d_U)$ . In addition, Alice and Bob will have their, public, identification strings $l_A$ and $l_B$ .Structure of challenge-response protocols: 	<ul> <li>Alice identifies a communicating person as Bob if he can send her back r through e<sub>A</sub>(r, r<sub>1</sub>) for a random r<sub>1</sub>.</li> <li>Bob identifies a communicating person as Alice if she</li> </ul>	Static means of identification: People can be identified by their (a) attributes (fingerprints), possessions (passports), or knowledge. Dynamic means of identification: Challenge and respond protocols. Example: Let both Alice and Bob share a key k and a one-way function $f_k$ . Bob sends Alice a random number, or a random string, RAND. Alice sends Bob $PI = f_k(RAND)$ . If Bob gets PI, then he verifies whether $PI = f_k(RAND)$ . If ges, he starts to believe that the person he has communicated with is Alice (more exactly that Alice is the person who sent RAND to him). The process can be repeated to increase probability of a correct identification. MESSAGE AUTHENTICATION – to be discussed in details later MAC -method (Message Authentication Code) Let Alice and Bob share a key k and an encoding algorithm $A_k$ . To communicate a message m, Alice sends a pair( $m, A_k(m)$ ) – { $A_k(m)$ is said to be MAC}.
In a challenge-response identification protocol a party A proves its identity to a party B by demonstrating knowledge of a secret/method known to be associated with A only without revealing the secret/method itself to B. Structure of challenge-response protocols: Commitment (to a secret). Challenge	prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 9/75

Verification (of the response).	CHALLENGE-RESPONSE PROTOCOLS - A SPECIFICATION	THREE-WAY AUTHENTICATION and also KEY-AGREEMENT I

THREE-WAY AUTHENTICATION and KEY AGREEMENT II	DATA AUTHENTICATION
<ul> <li>Alice verifies Bob's signature sig<sub>sB</sub>(t<sub>1</sub>) with t<sub>1</sub> = (l<sub>A</sub>, r<sub>A</sub>, r<sub>B</sub>, c),, and then checks that the r<sub>A</sub> she just got matches the one she generated in Step 1. Once verified, she is convinced that she is communicating with Bob. She gets session key k via</li> <li>D<sub>dA</sub>(c) = D<sub>dA</sub>(E<sub>eA</sub>(k)) = k, sets t<sub>2</sub> = (l<sub>B</sub>, r<sub>B</sub>) and signs it as sig<sub>sA</sub>(t<sub>2</sub>). Then she sends m<sub>3</sub> = (t<sub>2</sub>, sig<sub>sA</sub>(t<sub>2</sub>)) to Bob.</li> <li>Bob verifies Alice's signature and checks that r<sub>B</sub> he just got matches his choice in Step 2. If both verifications pass, Alice and Bob have mutually authenticated each others identity and, in addition, have agreed upon a session key k.</li> </ul>	The goal of data authentication schemes (protocols) is to handle the case that data are sent through insecure channels. By creating a so-called Message Authentication Code (MAC) and sending this MAC, together with the message, through an insecure channel, one can create possibility to verify whether data were not changed in the channel. The price to pay is that communicating parties need to share a secret random key that needs to be transmitted through a secure channel.
prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 13/75	prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 14/75
SCHEMES for DATA AUTHENTICATION	FROM BLOCK CIPHERS to MAC – CBC-MAC
Basic difference between MACs and digital signatures is that MACs are symmetric in the following sense: Anyone who is able to verify MAC of a message is also able to generate the same MAC for that message. A scheme (M, T, K) for a data authentication is given by: M is a set of possible messages (data) T is a set of possible MACs – (tags) K is a set of possible keys Moreover, it is required that to each $k \in K$ there is a single and easy to compute authentication mapping $auth_k : \{0, 1\}^* \times M \to T$ and a single and easy to compute verification mapping $ver_k : M \times T \to \{true, false\}$ such that the following two conditions should be satisfied: Correctness: For each $m \in M$ and $k \in K$ it holds $ver_k(m, c) = true$ , if there exists an $r \in \{0, 1\}^*$ such that $c = auth_k(r, m)$ Security: For any $m \in M$ and any $k \in K$ it is computationally unfeasible, without a knowledge of k, to find $t \in T$ such that $ver_k(m, t) = true$	Let C be an encryption algorithm that maps k-bit strings into k-bit strings. If a message $m = m_1 m_2 \dots m_l$ is divided into blocks of length k, then so-called CBC-mode of encryption assumes a choice (random) of a special block $y_0$ of the length k, and performs the following computations, for $i = 1, \dots, l$ $y_i = C(y_{i-1} \oplus m_i)$ In such a case $y_1    y_2    \dots    y_l$ is the encryption of m and $y_l$ can be considered as the MAC for m. A modification of this method is to use another crypto-algorithm to encrypt the last block $m_l$ .

IV054 9. Identification, authentication, secret sharing and e-commerce

SPECIAL WEAKNESS of the CBS-MAC METHOD	FROM HASH FUNCTIONS TO HMAC
Let us have three pairs and in each pair a message and its MAC $(m_1, t_1), (m_2, t_2), (m_3, t_3)$ where messages $m_1, m_3$ and also $t_1, t_3$ are of the length k. In addition, let us have $m_2 = m_1   B   m'_2$ for some B that has also the length k. The encryption of the block B within $m_2$ using CBC-method will then be $C(B \oplus t_1)$ . If we now define $B' = B \oplus t_1 \oplus t_3, m_4 = m_3   B'   m'_2$ , then, during the encryption of $m_4$ , we get $C(B' \oplus t_3) = C(B \oplus t_1)$ , This implies that MAC's for $m_4$ and $m_2$ are the same. One can therefore forge a new valid pair	So called HMAC protocol was published as the internet standard RFC2104. Let a hash function h process messages by blocks of b bytes and produce a hash of 1 bytes and let t be the size of MAC, in bytes. HMAC of a message m with a key k is computed as follows: If k has more than b bytes replace k with h(k). Append zero bytes to k to have exactly b bytes. Compute (using constant strings opad and ipad) $h(k \oplus opad  h(k \oplus ipad  m))$ . and truncate the results to its t leftmost bytes to get $HMAC_k(m)$ . There is a variety of HMAC systems and they are usually specified by a hash function that is used
$(m_4, t_2).$

DISADVANTAGE of STATIC USER IDENTIFICATION SCHEMES	SIMPLIFIED Fiat-Shamir IDENTIFICATION SCHEME
DISADVANTAGE of STATIC USER IDENTIFICATION SCHEMES Everybody who knows your password or PIN can impersonate you.	A trusted authority (TA) chooses: large random primes p,q, computes $n = pq$ ; and chooses a quadratic residue $v \in QR_n$ , and s such that $s^2 = v \pmod{n}$ . public-key: v
	A trusted authority (TA) chooses: large random primes p,q, computes $n = pq$ ; and chooses a quadratic residue $v \in QR_n$ , and s such that $s^2 = v \pmod{n}$ .
Everybody who knows your password or PIN can impersonate you. Better are dynamic means of identification - for example so called	A trusted authority (TA) chooses: large random primes p,q, computes $n = pq$ ; and chooses a quadratic residue $v \in QR_n$ , and s such that $s^2 = v \pmod{n}$ . public-key: v private-key: s (that Alice knows, but not Bob)

<ul> <li>Alice chooses a random r &lt; n, computes x = r<sup>2</sup> mod n and sends x (her commitment) to Bob.</li> <li>Bob sends to Alice a random bit b (a challenge).</li> <li>Alice sends to Bob (a response) y = rs<sup>b</sup>.</li> <li>Complete the sender of the sender o</li></ul>	Analysis The first message is a commitment by Alice that she knows square root of x. The second message is a challenge by Bob. If Bob sends b = 0, then Alice has to open her commitment and reveal r. If Bob sends b = 1, the Alice has to show her secret s in an "encrypted form". The third message is Alice's response to the challenge of Bob.
prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 21/75 prof. Joze	ozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 22/75
HOW CAN BAD EVE CHEAT? Fiat-S	Shamir IDENTIFICATION SCHEME – PARALLEL VERSION
Eve can send, to fool Bob, as her commitment, either $r^2$ for a random r or $r^2v^{-1}$ In the first case Eve can respond correctly to the Bob's challenge b=0, by sending r; but cannot respond correctly to the challenge b = 1. In the second case Eve can respond correctly to Bob's challenge b = 1, by sending r again; but cannot respond correctly to the challenge b = 0. Eve has therefore a 50% chance to cheat.	Following parallel version of Fiat-Shamir identification scheme the probability of a dentification is decreased. See primes $p, q$ and compute $n = pq$ and choose as security parameters integers $k, t$ . See quadratic residues $v_1, \ldots, v_k \in QR_n$ . See quadratic residues $v_1, \ldots, v_k \in QR_n$ . Set $s_1, \ldots, s_k$ such that $s_i = \sqrt{v_i} \mod n$ Sc-key: $v_1, \ldots, v_k$ secret-key: $s_1, \ldots, s_k$ of Alice PROTOCOL: Alice chooses a random $r < n$ , computes $a = r^2 \mod n$ and sends a to Bob. Bob sends Alice a random k-bit string $b_1 \ldots b_k$ . Alice sends to Bob $y = r \prod_{i=1}^k s_i^{b_i} \mod n$ Bob accepts if and only if $y^2 = a \prod_{i=1}^k v_i^{b_i} \mod n$ and Bob repeat this protocol t times, until Bob is convinced that Alice knows $s_k$ . whence that Alice can fool Bob is $2^{-kt}$ , a significant decrease comparing with the $e \frac{1}{2}$ of the previous version of the identification scheme.

THE SCHNORR IDENTIFICATION SCHEME – SETTING	Schnorr IDENTIFICATION SCHEME - PROTOCOL
This is a practically attractive, because being computationally efficient (in time, space + communication) identification scheme, which minimizes storage + computations performed by Alice (to be, for example, a smart card). Scheme also requires a trusted authority (TA) who Chooses: a large prime $p < 2^{512}$ , a large prime q dividing $p - 1$ and $q \le 2^{140}$ , an $\alpha \in \mathbb{Z}_p^*$ of order q, a security parameter t such that $2^t < q$ , p, q, $\alpha$ , t are made public. establishes: a secure digital signature scheme with a secret signing algorithm $sig_{TA}$ and a public verification algorithm $ver_{TA}$ . Protocol for issuing a certificate to Alice TA establishes Alice's identity by conventional means and forms a 512-bit string ID(Alice) which contains the identification information. Alice chooses a secret random $0 \le a \le q - 1$ and computes $v = \alpha^{-a} \mod p$ and sends v to the TA. TA generates signature $s = sig_{TA}(ID(Alice), v)$ and sends to Alice as her certificate: C (Alice) = (ID(Alice), v, s)	<ul> <li>Alice chooses a random 0 ≤ k &lt; q and computes γ = α<sup>k</sup> mod p.</li> <li>Alice sends to Bob her certificate C (Alice) = (ID(Alice), v, s) and also γ.</li> <li>Bob verifies the signature of TA by checking that ver<sub>TA</sub>(ID(Alice), v, s) = true.</li> <li>Bob chooses a random 1 ≤ r ≤ 2<sup>t</sup>, where t &lt; lg q is a security parameter and sends it to Alice (often t ≤ 40).</li> <li>Alice computes and sends to Bob y = (k + ar) mod q.</li> <li>Bob verifies that γ ≡ α<sup>y</sup>v<sup>r</sup> mod p</li> <li>This way Alice proofs her identity to Bob. Indeed, α<sup>y</sup>v<sup>r</sup> ≡ α<sup>k+ar</sup>α<sup>-ar</sup> mod p ≡ α<sup>k</sup> mod p ≡ γ mod p.</li> <li>Total storage needed: 512 bits for ID(Alice), 512 bits for v, 320 bits for s (if DSS is used). In total – 1344 bits.</li> <li>Total communication needed from: Alice → Bob – 1996 (= 1344+512+140) bits, Bob → Alice 40 bits (to send r).</li> </ul>
prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 25/75	prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 26/75
Okamoto IDENTIFICATION SCHEME	Okamoto IDENTIFICATION SCHEME – BASICS ONCE MORE
The disadvantage of the Schnorr identification scheme is that there is no proof of its security. For the following modification of the Schnorr identification scheme presented below, for so called Okamoto identification scheme, a proof of security exists. Basic setting: To set up the scheme TA chooses: a large prime $p \le 2^{512}$ , a large prime $q \ge 2^{140}$ dividing p - 1; two elements $\alpha_1, \alpha_2 \in Z_p^*$ of the order q. TA makes public $p, q, \alpha_1, \alpha_2$ and keeps secret (also before Alice and Bob) $c = lg\alpha_1\alpha_2$ . Finally, TA chooses a signature scheme and a hash function. Issuing a certificate to Alice TA establishes Alice's identity and issues her identification string ID(Alice). Alice secretly and randomly chooses $0 \le a_1, a_2 \le q - 1$ and sends to TA $v = \alpha_1^{-a_1}\alpha_2^{-a_2} \mod p$ . TA generates a signature $s = sig_{TA}(ID(Alice), v)$ and sends to Alice the certificate	Basic setting TA chooses: a large prime $p \le 2^{512}$ , large prime $q \ge 2^{140}$ dividing p - 1; two elements $\alpha_1, \alpha_2 \in Z_p^*$ of order q. TA keep secret (also from Alice and Bob) $c = \lg_{\alpha_1} \alpha_2$ . Issuing a certificate to Alice a TA establishes Alice's identity and issues an identification string ID(Alice). Alice randomly chooses $0 \le a_1, a_2 \le q - 1$ and sends to TA. $v = \alpha_1^{-a_1} \alpha_2^{-a_2} \mod p$ . TA generates a signature $s = sig_{TA}(ID(Alice), v)$ and sends to Alice the certificate C (Alice) = (ID(Alice), v, s).

Okamoto IDENTIFICATION SCHEME	DATA (MESSAGE) INTEGRITY and AUTHENTICATION
Okamoto IDENTIFICATION SCHEME a Alice chooses random $0 \le k_1, k_2 \le q - 1$ and computes $\gamma = \alpha_1^{k_1} \alpha_2^{k_2} \mod p$ . a Alice sends to Bob her certificate (ID(Alice), v, s) and $\gamma$ . b Bob verifies the signature of TA by checking that $ver_{TA}(ID(Alice), v, s) = true$ . B Bob chooses a random $1 \le r \le 2^t$ and sends it to Alice. Alice sends to Bob $y_1 = (k_1 + a_1 r) \mod q; y_2 = (k_2 + a_2 r) \mod q$ . B Bob verifies $\gamma \equiv \alpha_1^{y_1} \alpha_2^{y_2} v^r \pmod{p}$	DATA (MESSAGE) INTEGRITY and AUTHENTICATION
prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 29/75	prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 30/75
DATA INTEGRITY and AUTHENTICATION PROBLEMS	AUTHENTICATION CODES
<ul> <li>One of the main features of the current information processing era is that it becomes more and more a data-driven era - society is accumulating enormous amounts of data and has big problems with its reliable storing and efficient processing.</li> <li>In general, data integrity refers to maintaining and assuring the accuracy and consistency of data over its real life cycle and becomes a very important feature of data base systems.</li> <li>The goal is to ensure accuracy, validity and correctness of data - from hardware, software and human errors.</li> <li>In database systems, data integrity is normally enforced by a series of so called integrity constrains/rules</li> <li>Closely related to data integrity problems is the problem of authentication of data at their transmissions.</li> <li>With the use of cryptographic techniques to deal with data authentication problem we deal briefly in the next.</li> </ul>	They provide methods to ensure authentication of data/messages – that a message has not been tampered/changed, and that the message originated with the presumed sender. The goal is to achieve authentication even in the presence of Mallot, a man in the middle, who can observe transmitted messages and replace them by messages of his own choice. Formally, an authentication code consists of: a A set M of possible messages. A set T of possible messages. A set K of possible authentication tags. A set K of possible keys. A set R of authentication algorithms $a_k : M \to T$ , one for each $k \in K$ Transmission process Alice and Bob jointly choose a secret key k. If Alice wants to send a message w to Bob, she sends (w, t), where $t = a_k(w)$ . If Bob receives (w, t) he computes $t' = a_k(w)$ and if $t = t'$ , then Bob accepts the message w as authentic.

prof. Jozef Gruska

prof. Jozef Gruska

ATTACKS and DECEPTION PROBABILITIES	THE AUTHENTICATION MATRIX - EXAMPLE
<text><text><text><text><text><text><text><text></text></text></text></text></text></text></text></text>	Let $M = T = Z_3$ , $K = Z_3 \times Z_3 - Z_3 = \{0, 1, 2\}$ . For $(i, j) \in K$ and $w \in M$ , let $t_{ij}(w) = (iw + j) \mod 3$ . Let the matrix key $\times$ message of authentication tags has the form $\frac{\underbrace{\text{Key} \ 0 \ 1 \ 2}{(0, 1) \ 1 \ 1 \ 1 \ 1}}{(0, 2) \ 2 \ 2 \ 2} \underbrace{(1, 0) \ 0 \ 1 \ 2}{(1, 1) \ 1 \ 2 \ 0}}$ Impersonation attack: Let us assume that Mallot picks a message w and tries to guess the correct authentication tag. Problem is that for each message w and each tag a there are exactly three keys k such that $t_k(w) = a$ . Hence $P_i = \frac{1}{3}$ . Substitution attack: By checking the table one can see that if Mallot observes an authenticated message (w, t), then there are exactly three possibilities for the key that was used. Moreover, for each choice (w', t'), $w \neq w'$ , there is exactly one of the three possible keys for (w',t') that can be used. Therefore $P_s = \frac{1}{3}$ .
ORTHOGONAL ARRAYS	CONSTRUCTION and BOUNDS for OAs
$\begin{array}{ c c c c c } \hline \text{Definition An orthogonal array OA(n, k, \lambda) is a \lambda n^2 \times k array of n symbols, such that in any two columns of the array every one of the possible n^2 pairs of symbols occurs in exactly \lambda rows. Example IA(3,3,1) obtained from the authentication matrix presented before; \begin{pmatrix} 0 & 0 & 0 \\ 1 & 1 & 1 \\ 2 & 2 & 2 \\ 0 & 1 & 2 \\ 1 & 2 & 0 \\ 2 & 0 & 1 \\ 0 & 2 & 1 \\ 1 & 0 & 2 \\ 2 & 1 & 0 \end{pmatrix} Theorem Suppose we have an orthogonal array OA(n, k, \lambda). Then there is an authentication code with  M  = k,  A  = n,  K  = \lambda n^2 and P_l = P_s = \frac{1}{n}. Proof Use each row of the orthogonal array as an authentication rule (key) with equal probability. Therefore we have the following correspondence: \begin{array}{c} \hline \text{orthogonal array} & \text{authentication rule} \\ \hline \text{row} & \text{authentication rule} \\ \hline \text{row} & \text{authentication rule} \\ \hline \text{symbol} & \text{authentication rag} \end{array}$	In an orthogonal array OA(n, k, $\lambda$ ) = n determines the number of authenticators (security of the code); = k is the number of messages the code can accommodate; = $\lambda$ relates to the number of keys $-\lambda n^2$ . The following holds for orthogonal arrays. = If p is prime, then OA(p, p, 1) exits. = Suppose there exists an OA(n, k, $\lambda$ ). Then $\lambda \ge \frac{k(n-1)+1}{n^2}$ ; = Suppose that p is a prime and $d \le 2$ an integer. Then there is an orthogonal array $OA(p, \frac{(p^d - 1)}{(p-1)}, p^{d-2})$ . = Let us have an authentication code with $ A  = n$ and $P_i = P_s = \frac{1}{n}$ . Then $ K  \ge n^2$ . Moreover, $ K  = n^2$ if and only if there is an orthogonal array $OA(n, k, 1)$ , where $ M  = k$ and $P_K(k) = \frac{1}{n^2}$ for every key $k \in K$ . The last claim shows that there are no much better approaches to authentication codes with deception probabilities as small as possible than orthogonal arrays.

--------------------	--	-------	--------------------	--	-------

COMMENTS on ORTHOGONAL ARRAYS	SECRET SHARING
<ul> <li>Orthogonal arrays are a very important concept of recreational mathematics, combinatorial mathematics, coding theory.</li> <li>They were introduced by Rao in 1946.</li> <li>One of the non-trivial questions is for which parameters one can construct the corresponding Orthogonal array.</li> <li>There is a library of more than 200 Orthogonal arrays.</li> </ul>	Secret sharing refers to methods for distribution a secret amongst a group of users (usually called players), using "shares of the secret", in such a way that only eligible groups of players can determine the secret by their cooperation and using their shares only. Secret sharing problem was discovered, as an important cryptographic primitive, independently by Adi Shamir and George Blakeley in 1979 and they also constructed first secret sharing protocols. For example, secret sharing is used as cryptographic primitive in several protocols for secure multiparty computation.
prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 37/75	prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 38/75
SECRET SHARING - PROBLEM	BASIC IDEA of the (n,t) THRESHOLD SECRET SHARING
<ul><li>In some applications, it is of importance to distribute a sensitive information, called here as a secret (for example an algorithm how to open a safe or a secret key) among several parties in such a way that only a well define subsets of parties can determine the secret - if members of the parties cooperate.</li><li>For example, in some cases one can increase security of confidential information, say a secret key, by sharing it between several parties.</li><li>In the following we show how to solve this problem in the following "threshold" setting:</li></ul>	In order to distribute a secret (number) S among <i>n</i> parties, the dealer creates a degree $t - 1$ random polynomial p such that $p(0)=S$ and distributes to each party as a "share" of the secret – a value of p in a separate point.

SECRET SHARING between TWO PARTIES THRESHOLD SECRET SHARING SCHEMES - FORM	VIALITIES
A dealer creates shares of a binary-string secret s and distributes them between two parties $P_1$ and $P_2$ by choosing a random binary string b, of the same length as s, and $\blacksquare$ sends b (as a "share" of s, to $P_1$ ) and $\blacksquare$ sends s $\oplus$ b, as a share of s, to $P_2$ . This way, none of the parties $P_1$ and $P_2$ alone has a slightest idea about s, but both together easily recover s by computing $b \oplus (s \oplus b) = s$ .	icient to assemble ut of three e vault. a method of a such a way that 1, or less, parties
The above scheme can be easily extended to the case of $n$ users so that only all of them can reveal the secret.	42/75
THE CASE $n = t$ BASIC PROPERTIES of SECURE SECRET SHARING	
Such a case is easy to deal with.All shares have to be "as large as the secret $(n, t)$ secret sharing scheme.In the case of an $m$ bit secret $S$ ,Indeed, any share $SH_i$ has to have the proposition shares can be seen as the secret $S$ .	erty that no
each but one of $n$ parties is assigned a different $m$ bit random number group of $t - 1$ of the remaining shares con- information about the secret, but adding the the secret can be obtained.	-
and the last participant gets as his share $X \oplus S$ , where X is xor of all remaining random shares. By xoring all shares the secret S is obtained. Therefore, Any share has to contain "no in about secret", but also "all information about secret" - both in some sense.	
By xoring all shares the secret <i>S</i> is obtained. All secure secret sharing schemes have to u elements. Prof. Jozef Gruska NU054 9. Identification, authentication, secret sharing and e-commerce	ise random

#### Shamir's (n,t)-THRESHOLD SCHEME

#### Initial phase:

Dealer D chooses a prime p, n randomly chosen integers  $x_i$ ,  $1 \le i \le n$  and sends  $x_i$  to the user  $P_i$ .

The values  $x_i$  are then made public.

**Share distribution:** Suppose that the dealer D wants to distribute a secret  $S \in Z_p$  among n parties. D randomly chooses, and keeps secret, t - 1 elements of  $Z_p$ ,  $a_1, \ldots, a_{t-1}$ . For  $1 \le i \le n$ , dealer D computes "shares"  $y_i = a(x_i)$ , where

$$a(x)=S+\sum_{j=1}^{t-1}a_jx^j \mod p$$

Finally, D sends the share  $y_i$  to the party  $P_i$ ,  $1 \le i \le n$  and keeps coefficients  $a_i$  secret. Secret accumulation: Let parties  $P_{i_1}, \ldots, P_{i_t}$  want to determine the secret S. Since, unknown to them, polynomial a(x) has degree t-1 they know that it has, in general, the form

$$a(x) = a_0 + a_1 x + \ldots + a_{t-1} x^{t-1}$$

and therefore they can determine all coefficients  $a_i$  from t equations  $a(x_{i_j}) = y_{i_j}$ , where all arithmetic is done modulo p.

It can be shown that equations obtained this way are linearly independent and the system has a unique solution.

IV054 9. Identification, authentication, secret sharing and e-commerc

In such a case  $S = a_0$ .

### Shamir's (n,t)-THRESHOLD SCHEME — SUMMARY

To distribute n shares of a secret S among parties  $P_1, \ldots, P_n$  a dealer - a trusted authority TA - proceeds as follows:

- TA chooses a prime  $p > max\{S, n\}$  and sets  $a_0 = S$ .
- TA selects randomly  $a_1, \ldots, a_{t-1} \in Z_p$  and creates the polynomial  $f(x) = \sum_{i=1}^{t-1} a_i x^i$ .
- TA computes  $s_i = f(i), i = 1, ..., n$  and transfers each  $(i, s_i)$  to the party  $P_i$  in a secure way.

Any group  ${\sf J}$  of  ${\sf t}$  or more parties can compute the secret. Indeed, from the previous corollary we have

$$S = a_0 = f(0) = \sum_{i \in J} f(i) \prod_{j \in J, j \neq i} \frac{j}{j-i}$$

In case |J| < t, then each  $a_0 \in Z_p$  is equally likely to be the secret.

#### Shamir's SCHEME — TECHNICALITIES

Shamir's scheme uses the following result concerning polynomials over fields  $Z_p$ , where p is prime.

Theorem Let 
$$f(x) = \sum_{i=0}^{t-1} a_i x^i \in Z_p[x]$$
 be a polynomial of degree t - 1 and let  

$$\Omega = \{(x_i, f(x_i)) \mid x_i \in Z_p, i = 1, \dots, t, x_i \neq x_i \text{ if } i \neq j\}$$

For any  $Q \subseteq \Omega$ , let  $P_Q = \{g \in Z_p[x] | deg(g) = t - 1, g(x) = y \text{ for all } (x,y) \in Q\}$ . Then it holds:

- P<sub>Ω</sub> = {f(x)}, i.e. f is the only polynomial of degree t 1, whose graph contains all t points in Ω.
- If Q is a proper subset of  $\Omega$  and  $x \neq 0$  for all  $(x, y) \in Q$ , then each  $a \in Z_p$  appears with the same frequency as the constant coefficient of polynomials in  $P_Q$ .

Corollary (Lagrange formula) Let  $f(x) = \sum_{i=0}^{t-1} a_i x^i \in Z_p[x]$  be a polynomial and let  $P = \{(x_l, f(x_i)) \mid i = 1, ..., t, x_i \neq x_j, i \neq j\}$ . Then

$$f(x) = \sum_{i=1}^{t} f(x_i) \prod_{1 \leq j \leq t, \quad j \neq i} \frac{x - x_j}{x_i - x_j}$$

**PROPERTIES of SHAMIR's SECRET** (n, t) **SHARING SCHEMES** 

IV054 9. Identification, authentication, secret sharing and e-commer

- Security: The scheme is information theoretically secure.
- Minimality: The size of each share does not exceed the size of the secret.
- Dynamicity: Shares can be replaced by another ones without affecting other shares.
- Flexibility: Parties can obtain different number of shares according to their importance (within an organization they are in).

ORTHOGONAL ARRAYS BASED SHARING SCHEME	SECRET SHARING – GENERAL CASE
<b>General form of orthogonal arrays:</b> An $t - (n, k, \lambda)$ orthogonal array for $t \le k$ is a $\lambda n^t \times k$ array, whose entries are from a set $X$ of $n$ points such that in every subset of $t$ columns of the array, every $t$ -tuple of points of $X$ appears in exactly $\lambda$ rows. A $t - (n, n + 1, 1)$ orthogonal array may be used to construct a perfect $(n, t)$ threshold secret sharing scheme, in the following way: Let $A$ be an $t - (v, n + 1, 1)$ orthogonal array. The first $n$ columns will be used to provide shares to the parties, while the last column represents the secret to be shared. If the dealer wishes to share a secret $S$ only the rows of $A$ where the last entry is $S$ are used in the scheme. The dealer then randomly selects one of these rows and sends out to the party $P_i$ the entry in this raw and in the column $i$ as the share.	<text><text><text><text><text><text><text></text></text></text></text></text></text></text>
EXAMPLE of an ACCESS STRUCTURE An access structure for the set of players $P = \{P_1, P_2, P_3, P_4, P_5\}$ is the set of subsets of $P$ that contains sets $\{P_2, P_5\}, \{P_1, P_4\}, \{P_1, P_2, P_3\}$ and all their supersets.	<ul> <li>SECRET SHARING SCHEME with VERIFICATION</li> <li>Secret sharing protocols increase security of a secret information by sharing it between several parties.</li> <li>Some secret sharing scheme are such that they work even in case some parties behave incorrectly.</li> <li>A secret sharing scheme with verification is such a secret sharing scheme that: <ul> <li>Each party P<sub>i</sub> is capable to verify correctness of his/her share s<sub>i</sub></li> <li>No party P<sub>i</sub> is able to provide incorrect information and to convince other parties about its correctness</li> </ul> </li> <li>In general, a player might lie about his own share, in order to gain information about other shares. Secret sharing schemes with verification allow players to be certain that no other players are lying about their shares.</li> </ul>

## Feldman's (n,k)-PROTOCOL

prof. Jozef Gruska

IV054 9. Identification, authentication, secret sharing and e-commerce

### Feldman's (n,k)-PROTOCOL - continuation

Feldman's protocol is an example of the secret sharing scheme with verification. The protocol is a generalization of Shamir's protocol. It is assumed that all n participants can broadcast messages to all others and each of them can determine all senders. Given are large primes $p, q, q (p-1), q > n$ and $h  generator of \mathbb{Z}_p^*. All these numbers, and also the number g = h^{\frac{p-1}{q}} \mod p, will be public.As in Shamir's scheme, to share a secret S, the dealer assigns to each party P_i a specific random x_i from \{1, \ldots, q-1\} and generates a random secret polynomialf(x) = \sum_{j=0}^{k-1} a_j x^j \mod q (1)such that f(0) = S and sends to each P_i the value y_i = f(x_i). In addition, using a broadcasting scheme, the dealer sends to each P_i all values v_j = g^{a_j} \mod p.$	Each $P_i$ verifies that $g^{y_i} = \prod_{j=0}^{k-1} (v_j)^{x_i^j} \mod p \qquad (1)$ If (1) does not hold, $P_i$ asks, using the broadcasting scheme, the dealer to broadcast correct value of $y_i$ . If there are at least k such requests, or some of the new values of $y_i$ does not satisfy (1), the dealer is considered as not reliable. One can easily verify that if the dealer works correctly, then all relations (1) hold.

E-COMMERCE Very important is to ensure security of e-money transactions needed for e-commerce. In addition to providing security and privacy, the task is also to prevent alterations of purchase orders and forgery of credit card information.	<ul> <li>BASIC REQUIREMENTS for e-COMMERCE SYSTEMS</li> <li>Authenticity: Participants in transactions cannot be impersonated and signatures cannot be forged.</li> <li>Integrity: Documents (purchase orders, payment instructions,) cannot be forged.</li> <li>Privacy: Details of transaction should be kept secret.</li> <li>Security: Sensitive information (as credit card numbers) must be protected.</li> <li>Anonymity: Anonymity of money senders should be guaranteed.</li> <li>Additional requirement: In order to allow an efficient fighting of the organized crime a system for processing e-money has to be such that under well defined conditions it has to be possible to revoke customer's identity and flow of e-money.</li> </ul>

CARDHOLDER and SHOP ACTIONS	BANK and SHOP ACTIONS
<ul> <li>CARDHOLDER and SHOP ACTIONS</li> <li>A cardholder performs the following procedure – to create GSO-goods and services order</li> <li>Computes HEGSO = h(e<sub>S</sub>(GSO)) – hash value of the encryption of GSO.</li> <li>Computes HEPI = h(e<sub>B</sub>(PI)) – hash value of the encryption of the payment instructions for the bank.</li> <li>Computes HPO = h(HEPI  HEGSO) – Hash value of the Payment Order.</li> <li>Signs HPO by computing "Dual Signature" DS = d<sub>C</sub>(HPO).</li> <li>Sends e<sub>S</sub>(GSO), DS, HEPI, and e<sub>B</sub>(PI) to the shop.</li> <li>The Shop does the following: – to create payment instructions</li> <li>Calculates h(e<sub>S</sub>(GSO)) = HEGSO;</li> <li>Calculates h(HEPI HEGSO) and e<sub>C</sub>(DS). If they are equal, the shop has verified by that the cardholder signature;</li> <li>Computes d<sub>S</sub>(e<sub>S</sub>(GSO)) to get GSO.</li> <li>Sends HEGSO, HEPI, e<sub>B</sub>(PI), and DS to the bank.</li> </ul>	<ul> <li>BANK and SHOP ACTIONS</li> <li>The Bank has received HEPI, HEGSO, e<sub>B</sub>(PI), and DS and performs the following actions.</li> <li>Computes h(e<sub>B</sub>(PI)) – which should be equal to HEPI.</li> <li>Computes h(h(e<sub>B</sub>(PI))  HEGSO) which should be equal to e<sub>C</sub>(DS) = HPO.</li> <li>Computes d<sub>B</sub>(e<sub>B</sub>(PI)) to obtain PI;</li> <li>Returns an encrypted (with e<sub>S</sub>) digitally signed authorization to shop, guaranteeing the payment.</li> <li>Shop completes the procedure by encrypting, with e<sub>C</sub>, the receipt to the cardholder, indicating that transaction has been completed.</li> <li>It is easy to verify that the above protocol fulfills basic requirements concerning security, privacy and integrity.</li> </ul>

DIGITAL MONEY	BLIND SIGNATURES – APPLICATIONS
<ul> <li>Is it possible to have electronic (digital) money?</li> <li>It seems that not, because copies of digital information are indistinguishable from their origin and one could therefore hardly prevent double spending,</li> <li>T. Okamoto and K. Ohia formulated six properties digital money systems should have.</li> <li>One should be able to send e-money through e-networks.</li> <li>It should not be possible to copy and reuse e-money.</li> <li>Transactions using e-money could be done off-line - that is no communication with central bank should be needed during translation.</li> <li>One should be able to sent e-money to anybody.</li> <li>An e-coin could be divided into e-coins of smaller values.</li> </ul>	Blind digital signatures allow the signer (bank) to sign a message without seeing its content. Scenario: Customer Bob would like to give e-money to Shop. E-moneys have to be signed by a Bank. Shop must be able to verify Bank's signature. Later, when Shop sends e-money to Bank, Bank should not be able to recognize that it signed these e-money for Bob. Bank has therefore to sign money blindly. Bob can obtain a blind signature for a message m from Bank by executing the Schnorr blind signature protocol described on the next slide. Basic setting Bank chooses large primes $p, q (p-1)$ and an $g \in Z_p$ of order q. Let $h: \{0, 1\}^* \to Z_p$ be a collision-free hash function. Bank's secret will be a randomly chosen $x \in \{0,, p-1\}$ . Public information: $(p, q, g, y = g^x)$ .

SOME BASIC CONCEPTS OF APPLIED CRYPTOGRAPHY	KEY AGREEMENT and AUTHENTICATION over INTERNET
<ul> <li>In applied cryptography literature the following concepts are often used:</li> <li>random string - a string obtained by tossing coins.</li> <li>nonce - a number that is used only once (in a use of a protocol).</li> <li>salt - a short random string.</li> <li>salting (padding) - attaching a short random string - a salt</li> <li>A use of such concepts will be illustrated in the next.</li> </ul>	<ul> <li>A variety of protocols have been developed to connect hosts on Internet. (Host are here those computers that provide services to other computers and users of Internet.)</li> <li>TCP/IP (Transmission Control Protocol/Internet protocol) is a set of communication protocols used to connect hosts on Internet.</li> <li>Important protocols are EKE (Encrypted Key Exchanged patented in 1993) and SPEKE (Simple Password Exponential key Exchange) and their various modifications.</li> <li>Of large importance is Secure Remote Protocol (SRP-6). In this protocol Alice interacts with Bob to establish a password k, and upon mutual authentication, a session key S is derived that is then used to establish a "permanent" key, to be used to encrypt all future traffic.</li> </ul>
prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 65/75	prof. Jozef Gruska IV054 9. Identification, authentication, secret sharing and e-commerce 66/75
SRP-6 PROTOCOL	
<ul> <li>Public values: A large prime p is chosen, such that (p − 1)/2 is also prime, a primitive root α modulo p is chosen as well as a hash function h. Protocol:</li> <li>To establish a password k with Bob, Alice picks a salt s and computes d = h(s, k), v = α<sup>d</sup>(mod p). Bob stores v and s as Alice's password and salt.</li> <li>Alice sends to Bob her identification l<sub>a</sub> and A = α<sup>a</sup>, where a is a nonce.</li> <li>Bob looks up Alice's password entry, retrieves v and s from her database and sends both s and B = 3v + α<sup>b</sup>, where b is another nonce, to Alice.</li> <li>Alice and Bob compute, independently, u = h(A, B).</li> <li>Alice computes S = (B - 3α<sup>d</sup>)<sup>(a+ud)</sup>. Bob independently computes S = (Av<sup>u</sup>)<sup>b</sup>.</li> <li>Both, Alice and Bob compute K = h(S).</li> </ul>	

To verify that she has the correct key, Alice sends to Bob

 $h_1 = h(h(p \oplus h(\alpha)), h(I_a), s, A, B, K).$ 

- Bob computes  $h_1$ , compares with value received from Alice and if they agree, he sends to Alice  $h_2 = h(A, h_1, K)$ .
- **I** Upon receiving  $h_2$  Alice verifies that K is a correct key.
