CODING, CRYPTOGRAPHY and CRYPTOGRAPHIC PROTOCOLS prof. RNDr. Jozef Gruska, DrSc. Faculty of Informatics Masaryk University November 22, 2016	Part I Identification, authentication, secret sharing and e-commerce
WORDS of CONSCIOUSNESS	CHAPTER 9: AUTHENTICATION, SECRET SHARING and e-COMMERCE
Keep in mind that a cryptosystem is as secure as its weakest part - security does not add up!	W1 1 detication, setter Status

CONTENTS I USER IDENTIFICATION and MESSAGE AUTHENTICATION/INTEGRITY	CONTENTS II SECRET SHARING and E-COMMERCE
 Most of today's cryptographic applications ask for identification of communicating parties, and/or for data integrity/authentication during communication, rather than for secrecy of transferring data. Main related problems to deal with are: User identification (authentication): How can a person/computer prove her/his identity? Message authentication: Can tools be provided to find out, for the recipient, that the message is indeed from the person who was supposed to send it? Message integrity (authentication): Can tools be provided to decide for the recipient whether or not the message was changed on the fly? Important practical objectives are to find identification schemes that are so simple that they can be implemented on smart cards – they are essentially credit cards equipped with a chip that can perform arithmetical operations and communications. 	 Secret sharing problem is the problem how to share a "secret" among a group of users in such a way that only well specified subsets of them can determine the secret. Secret sharing schemes are ideal, for example, for storing information that is highly sensitive and important. For example, for encryption keys. Secret sharing protocols/schemes are another often used cryptographic primitives, with a variety of applications, we will deal with in second part of this chapter. E-commerce: One of the main new applications of the cryptographic techniques is to establish secure and convenient manipulation with digital money (e-money), especially for e-commerce. An example how e-commerce can be realized, in a simplified setting, will be shown at the end of this chapter.
With all of the above problems we will deal in the first part of this chapter. prof. Jozef Gruska IV054 1. Identification, authentication, secret sharing and e-commerce 5/70	prof. Jozef Gruska IV054 1. Identification, authentication, secret sharing and e-commerce 6/70
prof. Jozef Gruska IV054 1. Identification, authentication, secret sharing and e-commerce 5/70 USER IDENTIFICATION (AUTHENTICATION)	prof. Jozef Gruska IV054 1. Identification, authentication, secret sharing and e-commerce 6/70 OBJECTIVES of IDENTIFICATIONS
 User identification (authentication) is a process at which one party (often referred to as a Prover or as Alice), convinces another party (often referred to as a Verifier or as Bob) of Prover's identity. Namely, that the Prover (Alice) convinces the other party that she has indeed participated (or is participating) in the identification process. In other words that the Prover has been herself active in proving her identity in the time the confirmative evidence of her identity has been required. The purpose of any identification (authentication) process is to preclude (vylucit) some impersonation (zosobnenie) of one person (the Prover) by someone else. 	 User identification process has to satisfy the following objectives: The Verifier will accept Prover's identity if both parties are honest; The Verifier cannot later, after participating in a successful identification, learn how to act as the Prover and to identify himself (as the Prover) to another verifier; A third party (called attacker here), say <i>E</i>, following the identification process of the Prover to the Verifier, has only a negligible chance to identify itself to someone else successfully as the Prover; Each of the above conditions should remain valid even if an attacker has observed, or has even participated in, several identification processes of the same party.

USER IDENTIFICATION PROTOCOLS

IDENTIFICATION SYSTEM BASED on a PKC

Identification protocols have to satisfy two security conditions:

- If one party, say Bob (a Verifier), gets a message from the other party, that claims to be Alice (a Prover), then Bob should be able to verify that the sender was indeed Alice.
- There should be no way to pretend, for a third party, say Charles, when communicating with Bob, that he is Alice without Bob having a large chance to find that out.

- Alice chooses a random r and sends $e_B(r)$ to Bob.
- \blacksquare Alice identifies a communicating person as Bob if he can send her back r.
- \blacksquare Bob identifies a communicating person as Alice if she can send him back r.

A potential misuse of the above system

We show that (any non-honest) Alice could misuse the above identification scheme.

Indeed, Alice could intercept a communication of Jane (some new "player") with Bob, and get a cryptotext $e_B(w)$, the one Jana has been sending to Bob, and then Alice could send $e_B(w)$ to Bob.

Honest Bob, who always follows fully the protocol, would then return ${\bf w}$ to Alice and she would get this way the plaintext ${\bf w}.$

IDENTIFICATION SYSTEM BASED	, , , , , , , , , , , , , , , , , , ,

THREE-WAY AUTHENTICATION and also KEY-AGREEMENT I	THREE-WAY AU
---	--------------

THREE-WAY AUTHENTICATION and KEY AGREEMENT II

 In this protocol a PKC will be used with encryption/decryption algorithms (e_U, d_U), for each user U, and a DSS with signing/verification algorithms(s_U, v_U). In addition, Alice and Bob will have their, public, identification strings I_A and I_B. ■ Alice chooses a random integer r_A, sets t = (I_B, r_A), signs it as sig_{sA}(t) and sends m₁ = (t, sig_{sA}(t)) to Bob. ■ Bob verifies Alice's signature, chooses a random r_B and a random session key k. He then encrypts k with Alice's public key to get E_{eA}(k) = c, sets t₁ = (I_A, r_A, r_B, c), and signs it as sig_{sB}(t₁). Then he sends m₂ = (t₁, sig_{sB}(t₁)) to Alice. 	 Alice verifies Bob's signature sig_s(t₁) with t₁ = (l_A, r_A, r_B, c),, and then checks that the r_A she just got matches the one she generated in Step 1. Once verified, she is convinced that she is communicating with Bob. She also gets the session key k via computation D_{d_A}(c) = D_{d_A}(E_{eA}(k)) = k, sets t₂ = (l_B, r_B) and signs it as sig_s(t₂). Then she sends m₃ = (t₂, sig_s(t₂)) to Bob. Bob verifies Alice's signature and checks that r_B he just got matches his choice in Step 2. If both verifications pass, Alice and Bob have mutually authenticated each others identity and, in addition, have agreed upon a session key k.
DATA AUTHENTICATION	SCHEMES for DATA AUTHENTICATION
<text><text><text><page-footer></page-footer></text></text></text>	Basic difference between MACs and digital signatures is that MACs are symmetric in the following sense: Anyone who is able to verify MAC of a message is also able to generate the same MAC for that message. A scheme (M, T, K) for a data authentication is given by: M is a set of possible messages (data) T is a set of possible messages (data) K is a set of possible MACs – (tags) K is a set of possible keys Moreover, it is required that to each $k \in K$ there is a single and easy to compute authentication mapping $auth_k : \{0,1\}^* \times M \to T$ and a single and easy to compute verification mapping $ver_k : M \times T \to \{true, false\}$ such that the following two conditions should be satisfied: Correctness: For each $m \in M$ and $k \in K$ the following holds: $ver_k(m, c) = true$ if there exists an $r \in \{0,1\}^*$ such that $c = auth_k(r,m)$ Security: For any $m \in M$ and any $k \in K$ it is computationally unfeasible, without a knowledge of k, to determine $t \in T$ such that $ver_k(m, t) = true$

FROM BLOCK CIPHERS to MAC – CBC-MAC	SPECIAL WEAKNESS of the CBS-MAC METHOD
FROM BLOCK CIPHERS to MAC – CBC-MAC Let C be an encryption algorithm that maps k-bit strings into k-bit strings. If a message $m = m_1 m_2 \dots m_l$ is divided into blocks of length k, then so-called CBC-mode of encryption assumes a choice (random) of a special block y_0 of the length k, and performs the following computations, for $i = 1, \dots, l$ $y_i = C(y_{i-1} \oplus m_i)$	SPECIAL WEAKNESS of the CBS-MAC METHOD Let us have three pairs and in each pair a message and its MAC $(m_1, t_1), (m_2, t_2), (m_3, t_3)$ where messages m_1, m_3 and also t_1, t_3 are of the length k. In addition, let us have $m_2 = m_1 B m'_2$ for some B that has also the length k. The encryption of the block B within m_2 using CBC-method will then be $C(B \oplus t_1)$. If we now define
In such a case	$B'=B\oplus t_1\oplus t_3,\ m_4=m_3\ B'\ m_2'$,
$y_1 \ y_2 \ \cdots \ y_l$	then, during the encryption of m_4 , we get
is the encryption of m and	${\mathcal C}(B'\oplus t_3)={\mathcal C}(B\oplus t_1),$
y_l can be considered as the MAC for m. A modification of this method is to use another crypto-algorithm to encrypt the last	This implies that MAC's for m_4 and m_2 are the same. One can therefore forge a new valid pair
block m_l .	$(m_4, t_2).$

FROM HASH FUNCTIONS TO HMAC	DISADVANTAGE of STATIC USER IDENTIFICATION SCHEMES
FROM HASH FUNCTIONS TO HMACSo called HMAC protocol was published as the internet standard RFC2104.Let a hash function h produce hashes of b bytes and let t be the size of the resulting MAC, in bytes. HMAC of a message m with a key k is computed as follows:= If k has more than b bytes replace k with h(k).= If k has less than b bytes than it is with zeros padded.= Compute (using constant b-bytes strings opad and ipad) $h(k \oplus opad h(k \oplus ipad m)).$ and truncate the results to its t leftmost bytes to get $HMAC_k(m)$.In HMAC ipad (opad) consists of b bytes equal to 0×36 ($0 \times 5c$) hexadecimal.There is a variety of HMAC systems and they are usually specified by a hash function that is used.The above version of HMAC was motivated by the existence of attacks for more trivial mechanisms for combining a key with a hash function.	 DISADVANTAGE of STATIC USER IDENTIFICATION SCHEMES Everybody who knows your password or PIN can impersonate you. Better are dynamic means of identification - for example so called challenge and response (or challenge-response) protocols. Basic idea of such protocols: Let Alice be known to have a capability to solve some hard problem P. Bob challenges a party claimed to be Alice by asking her to solve a particular instance of the P problem. If the party succeeds, Bob intends to believe that he is indeed communicating with Alice. Using so called zero-knowledge identification schemes, discussed in the next chapter, you can identify yourself without giving to the identificator the ability to impersonate you.

CHALLENGE-RESPONSE PROTOCOLS - A GENERAL SPECIFICATION	BASIC Fiat-Shamir IDENTIFICATION SCHEME
In a challenge-response identification protocol a party A proves its identity to a party B by demonstrating knowledge of a secret/method known to be associated with A only, without revealing the secret/method itself to B. Structure of challenge-response protocols: Commitment (to a secret). Challenge. Response. Verification (of the response).	 A trusted authority (TA) chooses: large random primes p,q, computes n = pq; and chooses a quadratic residue v ∈ QR_n, and s such that s² = v (mod n). public-key: v private-key: s (that Alice knows, but not Bob) Challenge-response Identification protocol Alice chooses a random r < n, computes x = r² mod n and sends x, her commitment, to Bob. Bob sends to Alice a random bit (a challenge) b. Alice sends Bob (a response) y = rs^b mod n Bob identifies the sender as Alice if and only if, verification, y² = xv^b mod n, which is taken as a proof that the sender knows square roots of x and of v. This protocol is a so-called single accreditation protocol Alice proves her identity by convincing Bob that she knows the square root s of v (without revealing s to Bob) and the square root r of x. If protocol is repeated t times, Alice has a chance 2^{-t} to fool Bob if she does not know s and r.
prof. Jozef Gruska IV054 1. Identification, authentication, secret sharing and e-commerce 21/70	prof. Jozef Gruska IV054 1. Identification, authentication, secret sharing and e-commerce 22/70
ANALYSIS of Fiat-Shamir IDENTIFICATION I	ANALYSIS of Fiat-Shamir IDENTIFICATION II
 public-key: v private-key: s (of Alice) such that s² = v (mod n). Protocol Alice chooses a random r < n, computes x = r² mod n and sends x (a commitment) to Bob. Bob sends to Alice a random bit b (a challenge). Alice sends to Bob (a response) y = rs^b. Bob verifies (a verification) if and only if y² = xv^b mod n, proving that Alice knows a square root of x. 	 Analysis The first message is a commitment by Alice that she knows square root of x. The second message is a challenge by Bob. If Bob sends b = 0, then Alice has to open her commitment and reveal r. If Bob sends b = 1, the Alice has to show her secret s in an "encrypted form". The third message is Alice's response to the challenge of Bob. Completeness: If Alice knows s, and both Alice and Bob follow the protocol, then the response rs^b is the square root of xv^b.

HOW CAN BAD EVE CHEAT?

Eve can send, to fool Bob, as her commitment, either r^2 for a random r or r^2v^{-1} In the first case Eve can respond correctly to the Bob's challenge b=0, by sending r; but cannot respond correctly	false identification is decreased. Choose primes p, q and compute $n = pq$ and choose as security parameters integers k, t . Choose quadratic residues $v_1, \ldots, v_k \in QR_n$. Compute s_1, \ldots, s_k such that $s_i = \sqrt{v_i} \mod n$ public-key: v_1, \ldots, v_k secret-key: s_1, \ldots, s_k of Alice PROTOCOL: I Alice chooses a random $r < n$, computes $a = r^2 \mod n$ and sends a to Bob. Bob sends Alice a random k-bit string $b_1 \ldots b_k$.
to the challenge $b = 1$.	Alice sends to Bob $x = r \prod_{i=1}^{k} s^{b_i} \mod n$
In the second case Eve can respond correctly to Bob's challenge $b = 1$, by sending r again; but cannot respond correctly to the challenge $b = 0$.	$y = r \prod_{i=1}^{k} s_i^{b_i} \mod n$ $ I = Bob accepts if and only if y^2 = a \prod_{i=1}^{k} v_i^{b_i} \mod n $
Eve has therefore a 50% chance to cheat.	Alice and Bob repeat this protocol t times, until Bob is convinced that Alice knows s_1, \ldots, s_k .
	The chance that Alice can fool Bob is 2^{-kt} , a significant decrease comparing with the chance $\frac{1}{2}$ of the previous version of the identification scheme.

THE SCHNORR IDENTIFICATION SCHEME – SETTING	Schnorr IDENTIFICATION SCHEME - PROTOCOL
This is a practically attractive, (computationally efficient, in time, space + communication) identification scheme, which minimizes storage + computations	Alice chooses a random $0 \le k < q$ and computes $\alpha = \alpha^k \mod n$

performed by Alice (to be, for example, a smart card).

Scheme also requires a trusted authority (TA) who

1 chooses: a large prime $p < 2^{512}$, a large prime q dividing p - 1 and $q \leq 2^{140}$, an $\alpha \in Z_p^*$ of order q,

a security parameter t such that $2^t < q$, p, q, α , t are made public.

2 establishes: a secure digital signature scheme with a secret signing algorithm signate and a public verification algorithm ver_{TA}.

Protocol for issuing a certificate to Alice

- **I** TA establishes Alice's identity by conventional means and forms a 512-bit string ID(Alice) which contains the identification information.
- 2 Alice chooses a secret random $0 \le a \le q 1$ and computes

$$v = \alpha^{-a} \mod p$$

and sends v to the TA.

TA generates signature

$$s = sig_{TA}(ID(Alice), v)$$

and sends to Alice as her certificate: C(Alice) = (ID(Alice), v, s)

$\gamma = \alpha^{\kappa} \mod p$. **2** Alice sends to Bob her certificate C (Alice) = (ID(Alice), v, s) and also γ . Bob verifies the signature of TA by checking that $ver_{TA}(ID(Alice), v, s) = true.$ Bob chooses a random $1 \le r \le 2^t$, where $t \le \lg q$ is a security parameter and sends it to Alice (often t < 40). Alice computes and sends to Bob $y = (k + ar) \mod q$. 6 Bob verifies that

 $\gamma \equiv \alpha^{y} v^{r} \mod p$

This way Alice proofs her identity to Bob. Indeed,

 $\alpha^{y} \mathbf{v}^{r} \equiv \alpha^{k+ar} \alpha^{-ar} \mod p$ $\equiv \alpha^k \mod p$ $\equiv \gamma \mod p$.

Total storage needed: 512 bits for ID(Alice), 512 bits for v, 320 bits for s (if DSS is used). In total - 1344 bits.

Total communication needed from: Alice \rightarrow Bob – 1996 (= 1344+512+140) bits, Bob \rightarrow Alice 40 bits (to send r).

Bob verifies the signature of TA by checking that $ver_{TA}(ID(Alice), v, s) = true.$ Bob chooses a random $1 \le r \le 2^t$ and sends it to Alice. Alice sends to Bob $y_1 = (k_1 + a_1 r) \mod q; y_2 = (k_2 + a_2 r) \mod q.$ Bob verifies $\gamma \equiv \alpha_1^{y_1} \alpha_2^{y_2} v^r \pmod{p}$	DATA (MESSAGE) INTEGRITY and AUTHENTICATION

DATA INTEGRITY and AUTHENTICATION PROBLEMS	AUTHENTICATION CODES
 One of the main features of the current information processing era is that it becomes more and more a data-driven era - society is accumulating enormous amounts of data and has big problems with its reliable and efficient storing, transmission and processing. In general, data integrity refers to maintaining and assuring the accuracy and consistency of data over their whole real life cycle and becomes a very important feature of database systems. The goal is to ensure accuracy, validity and correctness of data - a protection from hardware, software and human errors. In database systems, data integrity is normally enforced by a series of so called integrity constrains/rules. Closely related to data integrity problems is the problem of authentication of data at their transmissions. With the use of cryptographic techniques to deal with data authentication problem we deal briefly in the next. 	They provide methods to ensure authentication of data/messages – that a message has not been tampered/changed, and that the message originated with the presumed sender. The goal is to achieve authentication even in the presence of Mallot, a man in the middle, who can observe transmitted messages and replace them by messages of his own choice. Formally, an authentication code consists of: a A set M of possible messages. A set T of possible authentication tags. A set K of possible keys. A set R of authentication algorithms $a_k : M \to T$, one for each $k \in K$ Transmission process Alice and Bob jointly choose a secret key k. If Alice wants to send a message w to Bob, she sends (w, t), where $t = a_k(w)$. If Bob receives (w, t) he computes $t' = a_k(w)$ and if $t = t'$, then Bob accepts the message w as authentic.
prof. Jozef Gruska IV054 1. Identification, authentication, secret sharing and e-commerce 33/70	prof. Jozef Gruska IV054 1. Identification, authentication, secret sharing and e-commerce 34/70
ATTACKS and DECEPTION PROBABILITIES	THE AUTHENTICATION MATRIX - EXAMPLE
There are two basic types of attacks Mallot, the man in the middle, can do. Impersonation. Mallot introduces a message (w, t) into the channel – expecting that message will be received as being sent by Alice. Substitution. Mallot replaces a message (w, t) in the channel by another one, (w', t') – expecting that message will be accepted as being sent by Alice. With any impersonation (substitution) attack a probability $P_i(P_s)$ is associated that	Let $M = T = Z_3$, $K = Z_3 \times Z_3Z_3 = \{0, 1, 2\}$. For $(i, j) \in K$ and $w \in M$, let $t_{ij}(w) = (iw + j) \mod 3$. Let the matrix key \times message of authentication tags has the form $\frac{Key 0 1 2}{(0,0) 0 0 0}$ $(0,1) 1 1 1 1$ $(0,2) 2 2 2 2$ $(1,0) 0 1 2$ $(1,1) 1 2 0$ $(1,2) 2 0 1$ $(2,0) 0 2 1$

Mallot will deceive Bob, if Mallot follows an optimal strategy. In order to determine such probabilities we need to know probability distributions P_m on messages and P_k on keys.

In the following so called **authentication matrices** $|K| \times |M|$ will tabulate all authentication tags. The item in a row corresponding to a key k and in a column corresponding to a message w will contain the authentication tag $t_k(w)$.

The goal of authentication codes, to be discussed next, is to decrease probabilities that Mallot performs successfully impersonation or substitution.

Key	0	1	2
(0,0)	0	0	0
(0,1)	1	1	1
(0,2)	2	2	2
(1,0)	0	1	2
(1,1)	1	2	0
(1,2)	2	0	1
(2,0)	0	2	1
(2,1)	1	0	2
(2,2)	2	1	0

Impersonation attack: Let us assume that Mallot picks a message w and tries to guess the correct authentication tag.

Problem is that for each message w and each tag a there are exactly three keys k such that $t_k(w) = a$. Hence $P_i = \frac{1}{3}$.

Substitution attack: By checking the table one can see that if Mallot observes an authenticated message (w, a), then there are exactly three possibilities for the key that was used.

Moreover, for each choice (w', a'), $w \neq w'$, there is exactly one of the three possible keys for (w',a') that can be used. Therefore $P_s = \frac{1}{3}$.

ORTHOGONAL ARRAYS	CONSTRUCTION and BOUNDS for OAs	
Definition: An orthogonal array OA(n, k, λ) is a $\lambda n^2 \times k$ array of n symbols, such that in any two columns of the array every one of the possible n^2 pairs of symbols occurs in exactly λ rows.Example: IA(3,3,1) obtained from the authentication matrix presented before; $\begin{pmatrix} 0 & 0 & 0 \\ 1 & 1 & 1 \\ 2 & 2 & 2 \\ 0 & 1 & 2 \\ 1 & 2 & 0 \\ 2 & 0 & 1 \\ 0 & 2 & 1 \\ 1 & 0 & 2 \\ 2 & 1 & 0 \end{pmatrix}$ Theorem: Suppose we have an orthogonal array OA(n, k, λ). Then there is an authentication code with $ M = k, T = n, K = \lambda n^2$ and $P_I = P_s = \frac{1}{n}$.Proof: Use each row of the orthogonal array as an authentication rule (key) with equal probability. Therefore we have the following correspondence: $\frac{orthogonal array}{column}$ authentication rule column}authentication rule column}authentication rule column}authentication rule column}authentication rule column}authentication rule column}authentication rule column}authentication rule message authentication ruleProf. Jozef GrussWord 1. Metrification, autentation, secre sharing and e-commerceMathematication row columnProf. Jozef GrussWord 1. Metrification, autentication secre sharing and e-commerce	In an orthogonal array OA(n, k, λ) = n determines the number of authenticators/tags (security of the code); = k is the number of messages the code can accommodate; = λ relates to the number of keys $-\lambda n^2$. The following holds for orthogonal arrays. = If p is prime, then OA(p, p, 1) exits. = Suppose there exists an OA(n, k, λ). Then $\lambda \ge \frac{k(n-1)+1}{n^2}$; = Suppose that p is a prime and $d \le 2$ an integer. Then there is an orthogonal array $OA(p, \frac{(p^d - 1)}{(p-1)}, p^{d-2})$. = Let us have an authentication code with $ A = n$ and $P_i = P_s = \frac{1}{n}$. Then $ K \ge n^2$. Moreover, $ K = n^2$ if and only if there is an orthogonal array $OA(n, k, 1)$, where $ M = k$ and $P_K(k) = \frac{1}{n^2}$ for every key $k \in K$. The last claim shows that there are no much better approaches to authentication codes with deception probabilities as small as possible than orthogonal arrays.	
COMMENTS on ORTHOGONAL ARRAYS	SECRET SHARING	
 Orthogonal arrays are a very important concept of recreational mathematics, combinatorial mathematics, coding theory. They were introduced by Rao in 1946. One of the non-trivial questions is for which parameters one can construct the corresponding Orthogonal array. There is a library of more than 200 Orthogonal arrays. 	Secret sharing refers to methods for distribution a secret amongst a group of users (usually called players), using "shares of the secret", in such a way that only eligible groups of players can determine the secret by their cooperation and using their shares only. Secret sharing problem was discovered, as an important cryptographic primitive, independently by Adi Shamir and George Blakeley in 1979 and they also constructed first secret sharing protocols. For example, secret sharing is used as cryptographic primitive in several protocols for secure multiparty computation.

SECRET SHARING - PROBLEM	BASIC IDEA of the (n,t) THRESHOLD SECRET SHARING
In some applications, it is of importance to distribute a sensitive information, called here as a secret (for example an algorithm how to open a safe or a secret key) among several parties in such a way that only a well define subsets of parties can determine the secret - if members of the parties cooperate. For example, in some cases one can increase security of confidential information, say a secret key, by sharing it between several parties. In the following we show how to solve this problem in the following "threshold" setting: How to "partition" a number S (called here as a "secret") into n "shares" and distribute them among n parties in such a way that for a fixed (threshold) $t < n$ any t of parties can create S, but no $t - 1$, or less, of parties can have the slightest idea how to do that.	In order to distribute a secret (number) S among <i>n</i> parties, the dealer creates a degree $t - 1$ random polynomial p such that $p(0)=S$ and distributes to each party as a "share" of the secret – a value of p in a separate point. Since each degree $t - 1$ polynomial p is uniquely determined by any t points on p, the above distribution of points allows any t users to determine p, and so also p(0)=S, and no smaller group of parties, can have the slightest idea about S.

SECRET SHARING between TWO PARTIES	THRESHOLD SECRET SHARING SCHEMES - FORMALITIES
SECRET SHARING between TWO PARTIES A dealer creates shares of a binary-string secret s and distributes them between two parties P_1 and P_2 as follows: He chooses a random binary string b, of the same length as s, and \blacksquare sends b (as a "share" of s), to P_1 and \blacksquare sends $s \oplus b$ (as another share of s), to P_2 . This way, none of the parties P_1 and P_2 alone has a slightest idea about s, but both together easily recover s by computing $b \oplus (s \oplus b) = s$.	THRESHOLD SECRET SHARING SCHEMES - FORMALITIES An important special simple case of secret sharing schemes are threshold secret sharing schemes at which a certain threshold of participant is needed and sufficient to assemble the secret. For example, a vault in the bank can be opened only if at least two out of three responsible employees use their knowledge and tools (keys) to open the vault. Definition: Let $t \le n$ be positive integers. A (n, t)-threshold scheme is a method of sharing a secret S among a set P of n parties, $P = \{P_i 1 \le i \le n\}$, in such a way that any t, or more, parties can compute the value S , but no group of t - 1, or less, parties can compute S. Secret S is chosen by a "dealer" $D \notin P$. It is assumed that the dealer "distributes" the secret through shares to parties secretly and in such a way that no party knows shares of other parties.

THE CASE $n = t$	BASIC PROPERTIES of SECURE SECRET SHARING SCHEMES
Such a case is easy to deal with.	All shares have to be "as large as the secret" in an (n, t) secret sharing scheme.
In the case of an m bit secret S , each but one of n parties is assigned a different m bit random number and the last participant gets, as his share $X \oplus S$, where X is xor of all remaining random shares.	Indeed, any share SH_i has to have the property that no group of $t - 1$ of the remaining shares contains any information about the secret, but adding the share SH_i , the secret can be obtained. Therefore: (1) No share can contain "some information about secret"; (2) but also each share has to contain
By xoring all shares the secret S can be obtained.	 "all information about the secret" - both in some sense. All secure secret sharing schemes have to use random elements.

Shamir's (n,t)-THRESHOLD SCHEME	Shamir's SCHEME — TECHNICALITIES
Shamir's (n,t)-THRESHOLD SCHEMEInitial phase:Dealer D chooses a prime p, n randomly chosen integers x_i , $1 \le i \le n$ and sends x_i to the user P_i .The values x_i are then made public.Share distribution: Suppose that the dealer D wants to distribute a secret $S \in Z_p$ among n parties. (1) D randomly chooses, and keeps secret, t - 1 elements of Z_p , a_1, \ldots, a_{t-1} .(b) For $1 \le i \le n$, the dealer D computes "shares" $y_i = a(x_i)$, where $a(x) = S + \sum_{j=1}^{t-1} a_j x^j \mod p$.(3) Finally, D sends the share y_i to the party P_i , $1 \le i \le n$ and keeps coefficients a_i secret.Secret accumulation: Let parties P_{i_1}, \ldots, P_{i_t} want to determine the secret S. Since, unknown to them, polynomial $a(x)$ has degree t-1 they know that it has, in general, the form $a(x) = a_0 + a_1 x + \ldots + a_{t-1} x^{t-1}$,and therefore they can determine all coefficients a_i from t equations $a(x_i_j) = y_{i_j}$, where all arithmetic is done modulo p.	Shamir's SCHEME — TECHNICALITIES Shamir's scheme uses the following result concerning polynomials over fields Z_p , where p is prime. Theorem Let $f(x) = \sum_{i=0}^{t-1} a_i x^i \in Z_p[x]$ be a polynomial of degree t - 1 and let $\Omega = \{(x_i, f(x_i)) \mid x_i \in Z_p, i = 1,, t, x_i \neq x_j \text{ if } i \neq j\}$ For any $Q \subseteq \Omega$, let $P_Q = \{g \in Z_p[x] deg(g) \leq t - 1, g(x) = y \text{ for all } (x,y) \in Q\}$. Then it holds: $P_\Omega = \{f(x)\}, i.e. f is the only polynomial of degree t - 1, whose graph contains all t points in \Omega.If Q ext{ is a proper subset of } \Omega ext{ and } x \neq 0 ext{ for all } (x, y) \in Q, ext{ the each } a \in Z_p ext{ appears} ext{ with the same frequency as the constant coefficient of polynomials in } P_Q.Corollary: (Lagrange formula) Let f(x) = \sum_{i=0}^{t-1} a_i x^i \in Z_p[x] be a polynomial and letP = \{(x_i, f(x_i)) \mid i = 1,, t, x_i \neq x_j, i \neq j\}. Thenf(x) = \sum_{i=1}^{t} f(x_i) \prod_{1 \leq j \leq t, i \neq i} \frac{x - x_j}{x_i - x_j}$

To distribute **n** shares of a secret S among parties P_1, \ldots, P_n a dealer - a trusted authority TA - proceeds as follows:

- TA chooses a prime $p > max\{S, n\}$ and sets $a_0 = S$.
- TA selects randomly $a_1, \ldots, a_{t-1} \in Z_p$ and creates the polynomial $f(x) = \sum a_i x^i$.
- TA computes $s_i = f(i), i = 1, ..., n$ and transfers each (i, s_i) to the party P_i in a secure way.

Any group ${\sf J}$ of ${\sf t}$ or more parties can compute the secret. Indeed, from the previous corollary we have

$$S = a_0 = f(0) = \sum_{i \in J} f(i) \prod_{j \in J, j \neq i} \frac{j}{j-i}$$

IV054 1. Identification, authentication, secret sharing and e-commerc

In case |J| < t, then each $a_0 \in Z_p$ is equally likely to be the secret.

prof. Jozef Gruska

- Security: The scheme is information theoretically secure.
- Minimality: The size of each share does not exceed the size of the secret.
- Dynamicity: Shares can be replaced by another ones without affecting other shares.
- Flexibility: Parties can obtain different number of shares according to their importance (within an organization they are in).

SECRET SHARING SCHEME with VERIFICATION	Feldman's (n,k)-PROTOCOL
 Secret sharing protocols increase security of a secret information by sharing it between several parties. Some secret sharing scheme are such that they work even in case some parties behave incorrectly. A secret sharing scheme with verification is such a secret sharing scheme that: Each party P_i is capable to verify correctness of his/her share s_i No party P_i is able to provide incorrect information and to convince other parties about its correctness In general, a player might lie about his own share, in order to gain information about other shares. Secret sharing schemes with verification allow players to be certain that none of the other players is lying about his share. 	Feldman's protocol is an example of the secret sharing scheme with verification. The protocol is a generalization of Shamir's protocol. It is assumed that all n participants can broadcast messages to all others and each of them can determine all senders. Given are large primes $p, q, q (p-1), q > n$ and $h generator of \mathbb{Z}_p^*. All these numbers, and also the number g = h^{\frac{p-1}{q}} \mod p, will be public.As in Shamir's scheme, to share a secret S, the dealer assigns to each party P_i a specific random x_i from \{1, \ldots, q-1\} and generates a random secret polynomialf(x) = \sum_{j=0}^{k-1} a_j x^j \mod q (1)such that f(0) = S and sends to each P_i the value y_i = f(x_i). In addition, using a broadcasting scheme, the dealer sends to each P_i all values v_j = g^{a_j} \mod p.$
prof. Jozef Gruska IV054 1. Identification, authentication, secret sharing and e-commerce 53/70 Feldman's (n,k)-PROTOCOL - continuation	prof. Jozef Gruska IV054 1. Identification, authentication, secret sharing and e-commerce 54/70 Blakley's SECRET SHARING SCHEME
Each P_i verifies that $g^{y_i} = \prod_{j=0}^{k-1} (v_j)^{x_i^j} \mod p \qquad (1)$ If (1) does not hold, P_i asks, using the broadcasting scheme, the dealer to broadcast correct value of y_i . If there are at least k such requests, or some of the new values of y_i does not satisfy (1), the dealer is considered as not reliable. One can easily verify that if the dealer works correctly, then all relations (1) hold. Observe that $(v_j)^{x_i^j} - g^{a_j x_i^j}$ and therefore $g^{y_i} = \prod_{j=0}^{k-1} (v_j)^{x_i^j} \mod p = g(f(x_i))$	 This is a secret sharing scheme based on the following facts: Two nonparallel lines in the same plane intersect at exactly one point. Three nonparallel planes in space intersect in exactly one point. In general any <i>n</i> nonparallel (<i>n</i> – 1)-dimensional hyperplanes intersect in exactly one point. The secret can be therefore encoded as any single coordinate of the point of the intersection of <i>n</i> nonparallel (<i>n</i> – 1)-dimensional hyperplanes.

CARDHOLDER and SHOP ACTIONS
 A cardholder performs the following procedure – to create a GSO-goods and services order Computes HEGSO = h(e_S(GSO)) – the hash value of the encryption of GSO. Computes HEPI = h(e_B(PI)) – hash value of the encryption of the payment instructions for the bank. Computes HPO = h(HEPI HEGSO) – Hash value of the Payment Order. Signs HPO by computing "Dual Signature" DS = d_C(HPO). Sends e_S(GSO), DS, HEPI, and e_B(PI) to the shop. The Shop does the following: – to create payment instructions Calculates h(e_S(GSO)) = HEGSO; Calculates h(HEPI HEGSO) and e_C(DS). If they are equal, the shop has verified by that the cardholder signature; Computes d_S(e_S(GSO)) to get GSO. Sends HEGSO, HEPI, e_B(PI), and DS to the bank.
prof. Jozef Gruska IV054 1. Identification, authentication, secret sharing and e-commerce 62/70 DIGITAL MONEY
 Is it possible to have electronic (digital) money? It seems that not, because copies of digital information are indistinguishable from their origin and one could therefore hardly prevent double spending, T. Okamoto and K. Ohia formulated six properties digital money systems should have. One should be able to send e-money through e-networks. It should not be possible to copy and reuse e-money. Transactions using e-money could be done off-line – that is no communication with central bank should be needed during translation. One should be able to sent e-money to anybody. An e-coin could be divided into e-coins of smaller values. Several systems of e-money have been created that satisfy all or at least some of the above requirements.

BLIND SIGNATURES – APPLICATIONS	BLIND SIGNATURES – protocols
Blind digital signatures allow the signer (bank) to sign a message without seeing its content. Scenario: Customer Bob would like to give e-money to Shop. E-moneys have to be signed by a Bank. Shop must be able to verify Bank's signature. Later, when Shop sends e-money to Bank, Bank should not be able to recognize that it signed these e-money for Bob. Bank has therefore to sign money blindly. Bob can obtain a blind signature for a message m from Bank by executing the Schnorr blind signature protocol described on the next slide. Basic setting Bank chooses large primes $p, q (p-1)$ and an $g \in Z_p$ of order q. Let $h : \{0,1\}^* \to Z_p$ be a collision-free hash function. Bank's secret will be a randomly chosen $x \in \{0,, p-1\}$. Public information: $(p, q, g, y = g^x)$.	 Schnorr's simplified identification scheme in which Bank proves its identity by proving that it knows x. Bank chooses a random r ∈ {0,,q-1} and send a = g^r to Bob. {By that Bank "commits" itself to r? Bob sends to Bank a random c ∈ {0,,q-1} {a challenge}. Boh sends to Bob b = r - cx {a response}. Bob accepts the proof that bank knows x if a = g^by^c. {because y = g^x} Transfer of the identification scheme to a signature scheme: Bob chooses as c = h(m a), where m is the message to be signed. Signature: (c, b); Verification rule: a = g^by^c; Transcript: (a, c, b). Shnor's blind signature scheme Bob chooses random u, v, w ∈ {0,,q-1}, u ≠ 0, computes a = a'ug^vy^w, c = h(m a), c' = (c - w)u⁻¹ and sends c' to Bank. Bob verifies whether a' = g^{b'}y^{c'}, computes b = ub' + v and gets blind signature s(m) = (c, b) of m. Verification condition for the blind signature: c = h(m g^by^c). Both (a,c,b) and (a',c',b') are valid transcripts.

KEY AGREEMENT and AUTHENTICATION over INTERNET	SRP-6 PROTOCOL
 A variety of protocols have been developed to connect hosts on Internet. (Host are here those computers that provide services to other computers and users of Internet.) TCP/IP (Transmission Control Protocol/Internet protocol) is a set of communication protocols used to connect hosts on Internet. Important protocols are EKE (Encrypted Key Exchanged patented in 1903) and SPEKE (Simple Password Exponential key Exchange) and their various modifications. Of large importance is Secure Remote Protocol (SRP-6). In this protocol Alice interacts with Bob to establish a password k, and upon mutual authentication, a session key S is derived that is then used to establish a "permanent" key, to be used to encrypt all future traffic. 	 Public values: A large prime p is chosen, such that (p – 1)/2 is also prime, a primitive root α modulo p is chosen as well as a hash function h. Protocol: To establish a password k with Bob, Alice picks a salt s and computes d = h(s, k), v = α^d(mod p). Bob stores v and s as Alice's password and salt. Alice sends to Bob her identification l_a and A = α^a, where a is a nonce. Bob looks up Alice's password entry, retrieves v and s from her database and sends both s and B = 3v + α^b, where b is another nonce, to Alice. Alice and Bob compute, independently, u = h(A, B). Alice computes S = (B - 3α^d)^(s+ud). Bob independently computes S = (Av^u)^b. Both, Alice and Bob compute K = h(S). To verify that she has the correct key, Alice sends to Bob h₁ = h(h(p ⊕ h(\alpha)), h(l_a), s, A, B, K). Bob computes h₁, compares with value received from Alice and if they agree, he sends to Alice h₂ = h(A, h₁, K). Upon receiving h₂ Alice verifies that K is a correct key.
