#### Overview

- 2 Single-link/Complete-link
- 3 Centroid/GAAC
- 4 Labeling clusters

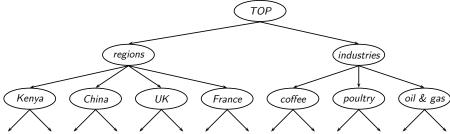

#### Take-away today

- Introduction to hierarchical clustering
- Single-link and complete-link clustering
- Centroid and group-average agglomerative clustering (GAAC)
- Bisecting K-means
- How to label clusters automatically

#### Hierarchical clustering

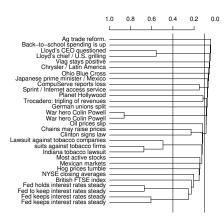

We want to create this hierarchy automatically. We can do this either top-down or bottom-up. The best known bottom-up method is hierarchical agglomerative clustering.

## Hierarchical agglomerative clustering (HAC)

- HAC creates a hierarchy in the form of a binary tree.
- Assumes a similarity measure for determining the similarity of two clusters.
- Up to now, our similarity measures were for documents.
- We will look at four different cluster similarity measures.

- Start with each document in a separate cluster
- Then repeatedly merge the two clusters that are most similar
- Until there is only one cluster.
- The history of merging is a hierarchy in the form of a binary tree.
- The standard way of depicting this history is a dendrogram.

# A dendrogram

- The history of mergers can be read off from bottom to top.
- The horizontal line of each merger tells us what the similarity of the merger was.
   We can cut the doptrocrease to a
- We can cut the dendrogram at a particular point (e.g., at 0.1 or 0.4) to get a flat clustering.

#### Divisive clustering

- Divisive clustering is top-down.
- Alternative to HAC (which is bottom up).
- Divisive clustering:
  - Start with all docs in one big cluster
  - Then recursively split clusters
  - Eventually each node forms a cluster on its own.
- ullet ightarrow Bisecting K-means at the end
- For now: HAC (= bottom-up)

Introduction

# Naive HAC algorithm

```
SIMPLEHAC(d_1, \ldots, d_N)
       for n \leftarrow 1 to N
   1
  2
      do for i \leftarrow 1 to N
  3
            do C[n][i] \leftarrow SIM(d_n, d_i)
  4
             I[n] \leftarrow 1 (keeps track of active clusters)
      A \leftarrow [] (collects clustering as a sequence of merges)
  5
      for k \leftarrow 1 to N-1
  6
   7
       do \langle i, m \rangle \leftarrow \arg \max_{\{\langle i, m \rangle: i \neq m \land I[i] = 1 \land I[m] = 1\}} C[i][m]
  8
            A.APPEND(\langle i, m \rangle) (store merge)
  9
            for i \leftarrow 1 to N
 10
            do (use i as representative for \langle i, m \rangle)
 11
                  C[i][j] \leftarrow SIM(\langle i, m \rangle, j)
 12
                  C[i][i] \leftarrow SIM(\langle i, m \rangle, j)
 13
             I[m] \leftarrow 0 (deactivate cluster)
 14
       return A
```

#### Computational complexity of the naive algorithm

- First, we compute the similarity of all *N* × *N* pairs of documents.
- Then, in each of N iterations:
  - We scan the  $O(N \times N)$  similarities to find the maximum similarity.
  - We merge the two clusters with maximum similarity.
  - We compute the similarity of the new cluster with all other (surviving) clusters.
- There are O(N) iterations, each performing a  $O(N \times N)$  "scan" operation.
- Overall complexity is  $O(N^3)$ .
- We'll look at more efficient algorithms later.

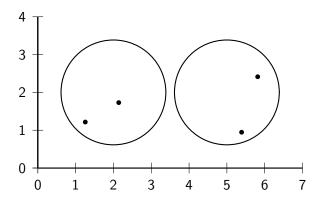

#### Key question: How to define cluster similarity

- Single-link: Maximum similarity
  - Maximum similarity of any two documents
- Complete-link: Minimum similarity
  - Minimum similarity of any two documents
- Centroid: Average "intersimilarity"
  - Average similarity of all document pairs (but excluding pairs of docs in the same cluster)
  - This is equivalent to the similarity of the centroids.
- Group-average: Average "intrasimilarity"
  - Average similary of all document pairs, including pairs of docs in the same cluster

peling clusters

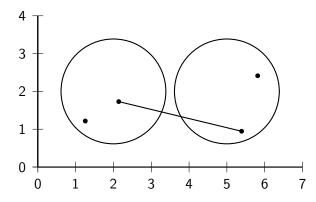

Variants

## Cluster similarity: Example

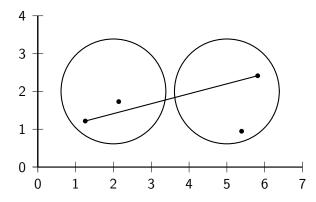

g clusters 🛛 🔪

#### Single-link: Maximum similarity

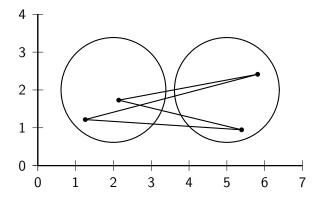

#### Complete-link: Minimum similarity

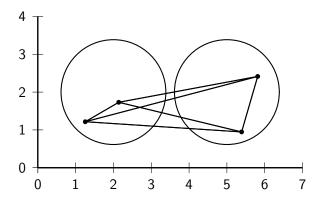

#### Centroid: Average intersimilarity

intersimilarity = similarity of two documents in different clusters

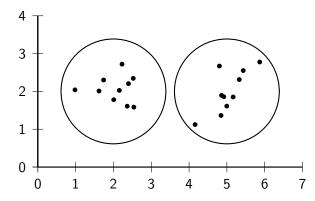

#### Group average: Average intrasimilarity

intrasimilarity = similarity of any pair, including cases where the two documents are in the same cluster

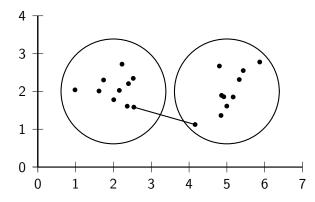

# Cluster similarity: Larger Example

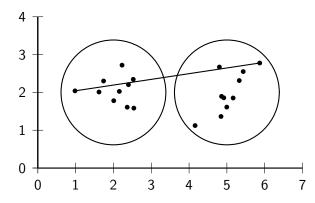

isters Vari

## Single-link: Maximum similarity

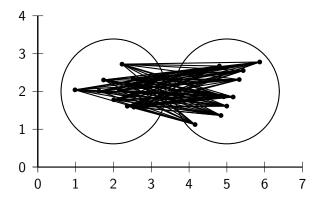

## Complete-link: Minimum similarity

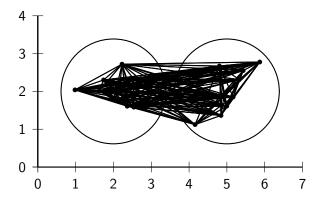

abeling clusters

Variants

## Centroid: Average intersimilarity

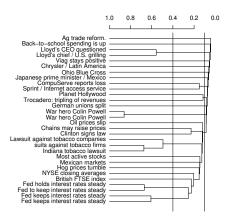

#### Group average: Average intrasimilarity

- The similarity of two clusters is the maximum intersimilarity the maximum similarity of a document from the first cluster and a document from the second cluster.
- Once we have merged two clusters, how do we update the similarity matrix?
- This is simple for single link:

 $\operatorname{SIM}(\omega_i, (\omega_{k_1} \cup \omega_{k_2})) = \max(\operatorname{SIM}(\omega_i, \omega_{k_1}), \operatorname{SIM}(\omega_i, \omega_{k_2}))$ 

dendrogram.

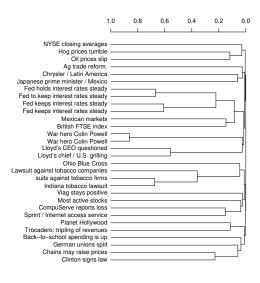

0 Notice: many small derived by cutting the There is no balanced clustering that can be to the main cluster members) being added clusters (1 or 2 2-cluster or 3-cluster

- The similarity of two clusters is the minimum intersimilarity the minimum similarity of a document from the first cluster and a document from the second cluster.
- Once we have merged two clusters, how do we update the similarity matrix?
- Again, this is simple:

$$\operatorname{SIM}(\omega_i, (\omega_{k_1} \cup \omega_{k_2})) = \min(\operatorname{SIM}(\omega_i, \omega_{k_1}), \operatorname{SIM}(\omega_i, \omega_{k_2}))$$

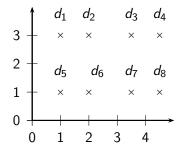

• We measure the similarity of two clusters by computing the diameter of the cluster that we would get if we merged them.

size.

 Notice that this dendrogram is much more balanced than the single-link one.
 We can create a 2-cluster clustering with two clusters of about the same

#### Exercise: Compute single and complete link clusterings

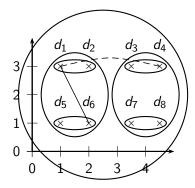

Introduction Single-link/Complete-link Centroid/GAAC Labeling clusters Variants

# Single-link clustering

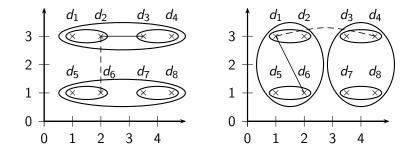

Introduction Single-link/Complete-link Centroid/GAAC Labeling clusters Variants

# Complete link clustering

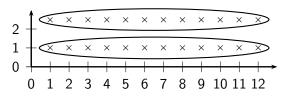

Variants

#### Single-link vs. Complete link clustering

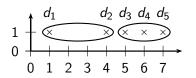

Introduction Single-link/Complete-link Centroid/GAAC Labeling clusters Variants
Single-link: Chaining

Single-link clustering often produces long, straggly clusters. For most applications, these are undesirable.

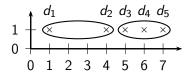

What 2-cluster clustering will complete-link produce?

Single-link/Complete-link

Coordinates:  $1 + 2 \times \epsilon, 4, 5 + 2 \times \epsilon, 6, 7 - \epsilon$ .

#### Complete-link: Sensitivity to outliers

- The complete-link clustering of this set splits *d*<sub>2</sub> from its right neighbors clearly undesirable.
- The reason is the outlier  $d_1$ .
- This shows that a single outlier can negatively affect the outcome of complete-link clustering.
- Single-link clustering does better in this case.

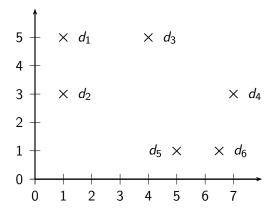

- The similarity of two clusters is the average intersimilarity the average similarity of documents from the first cluster with documents from the second cluster.
- A naive implementation of this definition is inefficient  $(O(N^2))$ , but the definition is equivalent to computing the similarity of the centroids:

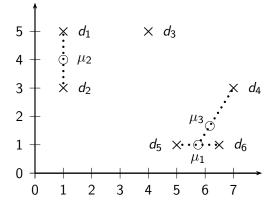

SIM-CENT
$$(\omega_i, \omega_j) = \vec{\mu}(\omega_i) \cdot \vec{\mu}(\omega_j)$$

- Hence the name: centroid HAC
- Note: this is the dot product, not cosine similarity!

## Exercise: Compute centroid clustering

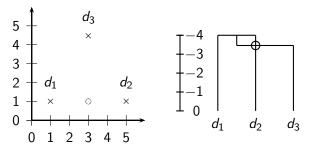

Introduction Single-link/Complete-link Centroid/GAAC Labeling clusters Variants

- In an inversion, the similarity increases during a merge sequence. Results in an "inverted" dendrogram.
- Below: Similarity of the first merger (d<sub>1</sub> ∪ d<sub>2</sub>) is -4.0, similarity of second merger ((d<sub>1</sub> ∪ d<sub>2</sub>) ∪ d<sub>3</sub>) is ≈ -3.5.

- Hierarchical clustering algorithms that allow inversions are inferior.
- The rationale for hierarchical clustering is that at any given point, we've found the most coherent clustering for a given K.
- Intuitively: smaller clusterings should be more coherent than larger clusterings.
- An inversion contradicts this intuition: we have a large cluster that is more coherent than one of its subclusters.
- The fact that inversions can occur in centroid clustering is a reason not to use it.

Centroid/GAAC

- GAAC also has an "average-similarity" criterion, but does not have inversions.
- The similarity of two clusters is the average intrasimilarity the average similarity of all document pairs (including those from the same cluster).
- But we exclude self-similarities.

# Group-average agglomerative clustering (GAAC)

Centroid/GAAC

• Again, a naive implementation is inefficient  $(O(N^2))$  and there is an equivalent, more efficient, centroid-based definition:

 $\operatorname{SIM-GA}(\omega_i, \omega_j) =$ 

$$\frac{1}{(N_i+N_j)(N_i+N_j-1)}[(\sum_{d_m\in\omega_i\cup\omega_j}\vec{d}_m)^2-(N_i+N_j)]$$

• Again, this is the dot product, not cosine similarity.

# Which HAC clustering should I use?

• Don't use centroid HAC because of inversions.

Centroid/GAAC

- In most cases: GAAC is best since it isn't subject to chaining and sensitivity to outliers.
- However, we can only use GAAC for vector representations.
- For other types of document representations (or if only pairwise similarities for documents are available): use complete-link.
- There are also some applications for single-link (e.g., duplicate detection in web search).

#### Flat or hierarchical clustering?

- For high efficiency, use flat clustering (or perhaps bisecting *k*-means)
- For deterministic results: HAC
- When a hierarchical structure is desired: hierarchical algorithm
- HAC also can be applied if K cannot be predetermined (can start without knowing K)

#### Major issue in clustering – labeling

- After a clustering algorithm finds a set of clusters: how can they be useful to the end user?
- We need a pithy label for each cluster.
- For example, in search result clustering for "jaguar", The labels of the three clusters could be "animal", "car", and "operating system".
- Topic of this section: How can we automatically find good labels for clusters?

- Come up with an algorithm for labeling clusters
- Input: a set of documents, partitioned into K clusters (flat clustering)
- Output: A label for each cluster
- Part of the exercise: What types of labels should we consider? Words?

- To label cluster  $\omega$ , compare  $\omega$  with all other clusters
- Find terms or phrases that distinguish  $\omega$  from the other clusters
- We can use any of the feature selection criteria we introduced in text classification to identify discriminating terms: mutual information,  $\chi^2$  and frequency.
- (but the latter is actually not discriminative)

## Non-discriminative labeling

- Select terms or phrases based solely on information from the cluster itself
  - E.g., select terms with high weights in the centroid (if we are using a vector space model)
- Non-discriminative methods sometimes select frequent terms that do not distinguish clusters.
- For example, MONDAY, TUESDAY, ... in newspaper text

#### Using titles for labeling clusters

- Terms and phrases are hard to scan and condense into a holistic idea of what the cluster is about.
- Alternative: titles
- For example, the titles of two or three documents that are closest to the centroid.
- Titles are easier to scan than a list of phrases.

#### Cluster labeling: Example

|    | ]      | labeling method  |   |  |  |  |  |
|----|--------|--|---|--|--|--|--|
|    | # docs | centroid   | mutual information  | title  |  |  |  |
| 4  | 622    | oil plant mexico pro-<br>duction crude <b>power</b><br><b>000 refinery gas</b> bpd | plant oil production<br>barrels crude bpd<br>mexico dolly capac-<br>ity petroleum       | MEXICO: Hurricane<br>Dolly heads for Mex-<br>ico coast     |  |  |  |
| 9  | 1017   | police security rus-<br>sian people military<br>peace killed told<br>grozny court  | police killed military<br>security peace told<br>troops forces rebels<br>people         | RUSSIA: Russia's<br>Lebed meets rebel<br>chief in Chechnya |  |  |  |
| 10 | 1259   | 00 000 tonnes traders<br>futures wheat prices<br>cents september<br>tonne          | <b>delivery</b> traders fu-<br>tures tonne tonnes<br><b>desk</b> wheat prices<br>000 00 | USA: Export Business<br>- Grain/oilseeds com-<br>plex      |  |  |  |

• Three methods: most prominent terms in centroid, differential labeling using MI, title of doc closest to centroid

• All three methods do a pretty good job.

Sojka, IIR Group: PV211: Hierarchical clustering

#### Bisecting K-means: A top-down algorithm

- Start with all documents in one cluster
- Split the cluster into 2 using K-means
- Of the clusters produced so far, select one to split (e.g. select the largest one)
- Repeat until we have produced the desired number of clusters

BISECTINGKMEANS
$$(d_1, \ldots, d_N)$$
  
1  $\omega_0 \leftarrow \{\vec{d}_1, \ldots, \vec{d}_N\}$   
2 *leaves*  $\leftarrow \{\omega_0\}$   
3 **for**  $k \leftarrow 1$  **to**  $K - 1$   
4 **do**  $\omega_k \leftarrow \text{PICKCLUSTERFROM}(leaves)$   
5  $\{\omega_i, \omega_j\} \leftarrow \text{KMEANS}(\omega_k, 2)$   
6 *leaves*  $\leftarrow leaves \setminus \{\omega_k\} \cup \{\omega_i, \omega_j\}$ 

7 return leaves

Introduction Single-link/Complete-link Centroid/GAAC Labeling clusters Variants Bisecting K-means

- If we don't generate a complete hierarchy, then a top-down algorithm like bisecting *K*-means is much more efficient than HAC algorithms.
- But bisecting *K*-means is not deterministic.
- There are deterministic versions of bisecting *K*-means (see resources at the end), but they are much less efficient.

Introduction

# Efficient single link clustering

```
SINGLELINKCLUSTERING(d_1, \ldots, d_N, K)
  1
       for n \leftarrow 1 to N
  2
       do for i \leftarrow 1 to N
  3
            do C[n][i].sim \leftarrow SIM(d_n, d_i)
  4
                 C[n][i].index \leftarrow i
  5
      I[n] \leftarrow n
  6
       NBM[n] \leftarrow \arg \max_{X \in \{C[n][i]: n \neq i\}} X.sim
  7 A \leftarrow []
      for n \leftarrow 1 to N-1
  8
  9
       do i_1 \leftarrow \arg \max_{\{i:I[i]=i\}} NBM[i].sim
 10
       i_2 \leftarrow I[NBM[i_1]].index]
 11 A.Append(\langle i_1, i_2 \rangle)
 12 for i \leftarrow 1 to N
            do if I[i] = i \land i \neq i_1 \land i \neq i_2
 13
 14
                    then C[i_1][i].sim \leftarrow C[i][i_1].sim \leftarrow \max(C[i_1][i].sim, C[i_2][i].sim)
 15
                 if I[i] = i_2
                    then I[i] \leftarrow i_1
 16
 17
            NBM[i_1] \leftarrow \arg \max_{X \in \{C[i_1][i]: I[i]=i \land i \neq i_1\}} X.sim
 18
       return A
```

- The single-link algorithm we just saw is  $O(N^2)$ .
- Much more efficient than the  $O(N^3)$  algorithm we looked at earlier!
- There are also  $O(N^2)$  algorithms for complete-link, centroid and GAAC.

Introduction

Combination similarities of the four algorithms
