Definition 1 (Time)

Mirriam-Webster: Time is the measured or measurable period during which an action, process, or condition exists or continues.

Definition 1 (Time)

Mirriam-Webster: Time is the measured or measurable period during which an action, process, or condition exists or continues.

Definition 2 (Real-time)

Real-time is a quantitative notion of time measured using a physical clock.

Example: After an event occurs (eg. temperature exceeds 500 degrees) the corresponding action (cooling) must take place within 100ms.

Compare with qualitative notion of time (before, after, eventually, etc.)

Definition 1 (Time)

Mirriam-Webster: Time is the measured or measurable period during which an action, process, or condition exists or continues.

Definition 2 (Real-time)

Real-time is a quantitative notion of time measured using a physical clock.

Example: After an event occurs (eg. temperature exceeds 500 degrees) the corresponding action (cooling) must take place within 100ms.

Compare with qualitative notion of time (before, after, eventually, etc.)

Definition 3 (Real-time system)

A *real-time system* must deliver services in a timely manner. **Not** necessarily fast, must satisfy some *quantitative* timing constraints

Definition 4 (Embedded system)

An *embedded system* is a computer system designed for specific control functions within a larger system, usually consisting of electronic as well as mechanical parts.

Real-time Embedded Systems

Definition 4 (Embedded system)

An *embedded system* is a computer system designed for specific control functions within a larger system, usually consisting of electronic as well as mechanical parts.

Most (not all) real-time systems are embedded

Most (not all) embedded systems are real-time

- chemical plant control
- automated assembly line (e.g. robotic assembly, inspection)

- chemical plant control
- automated assembly line (e.g. robotic assembly, inspection)

(Non-)Real-time (non-)embedded systems

There are real time systems that are not embedded:

- trading systems
- ticket reservation
- multimedia (on PC)
- ▶ ...

(Non-)Real-time (non-)embedded systems

There are real time systems that are not embedded:

- trading systems
- ticket reservation
- multimedia (on PC)
- ▶ ...

There are embedded systems that are (possibly) not real-time

e.g. a weather station sends data once a day without any deadline – not really real-time system

Caveat: Aren't all systems real-time in a sense?

Characteristics of Real-Time Embedded Systems

Real-time systems often are

- safety critical
 - Serious consequences may result if services are not delivered on timely basis
 - Bugs in embedded real-time systems are often difficult to fix
 - ... need to validate their correctness

Characteristics of Real-Time Embedded Systems

Real-time systems often are

- safety critical
 - Serious consequences may result if services are not delivered on timely basis
 - Bugs in embedded real-time systems are often difficult to fix
 - ... need to validate their correctness

concurrent

Real-world devices operate in parallel – better to model this parallelism by concurrent tasks in the program

... validation may be difficult, formal methods often needed

Characteristics of Real-Time Embedded Systems

Real-time systems often are

- safety critical
 - Serious consequences may result if services are not delivered on timely basis
 - Bugs in embedded real-time systems are often difficult to fix
 - ... need to validate their correctness

concurrent

- Real-world devices operate in parallel better to model this parallelism by concurrent tasks in the program
- ... validation may be difficult, formal methods often needed

reactive

- Interact continuously with their environment (as opposed to information processing systems)
- ... "traditional" validation methods do not apply

Given real-time requirements and an implementation on HW and SW, how to show that the requirements are met?

Given real-time requirements and an implementation on HW and SW, how to show that the requirements are met?

... testing might not suffice:

Maiden flight of space shuttle, 12 April 1981: 1/67 probability that a transient overload occurs during initialization; and it actually did!

Given real-time requirements and an implementation on HW and SW, how to show that the requirements are met?

Given real-time requirements and an implementation on HW and SW, how to show that the requirements are met?

... testing might not suffice:

Maiden flight of space shuttle, 12 April 1981: 1/67 probability that a transient overload occurs during initialization; and it actually did!

- We need a formal model and validation ...
- ... we need predictable behavior! It is difficult to obtain
 - caches, DMA, unmaskable interrupts
 - memory management
 - scheduling anomalies
 - difficult to compute worst-case execution time

Time sharing systems: minimize average response time The goal of scheduling in standard op. systems such as Linux and Windows

Time sharing systems: minimize average response time The goal of scheduling in standard op. systems such as Linux and Windows

Often it is **not** enough to minimize average response time! (A man drowned crossing a stream with an average depth of 15cm.)

Time sharing systems: minimize average response time The goal of scheduling in standard op. systems such as Linux and Windows

Often it is **not** enough to minimize average response time! (A man drowned crossing a stream with an average depth of 15cm.)

"hard" real-time tasks must be always finished before their deadline!

e.g. airbag in a car: whenever a collision is detected, the airbag must be deployed within 10ms

Time sharing systems: minimize average response time The goal of scheduling in standard op. systems such as Linux and Windows

Often it is **not** enough to minimize average response time! (A man drowned crossing a stream with an average depth of 15cm.)

"hard" real-time tasks must be always finished before their deadline!

e.g. airbag in a car: whenever a collision is detected, the airbag must be deployed within 10ms

Not all tasks in a real-time system are critical, only the quality of service is affected by missing a deadline

Time sharing systems: minimize average response time The goal of scheduling in standard op. systems such as Linux and Windows

Often it is **not** enough to minimize average response time! (A man drowned crossing a stream with an average depth of 15cm.)

"hard" real-time tasks must be always finished before their deadline!

e.g. airbag in a car: whenever a collision is detected, the airbag must be deployed within 10ms

Not all tasks in a real-time system are critical, only the quality of service is affected by missing a deadline

Most "soft" real-time tasks should finish before their deadlines.

e.g. frame rate in a videoconf. should be kept above 15fps most of the time

Time sharing systems: minimize average response time The goal of scheduling in standard op. systems such as Linux and Windows

Often it is **not** enough to minimize average response time! (A man drowned crossing a stream with an average depth of 15cm.)

"hard" real-time tasks must be always finished before their deadline!

e.g. airbag in a car: whenever a collision is detected, the airbag must be deployed within 10ms

Not all tasks in a real-time system are critical, only the quality of service is affected by missing a deadline

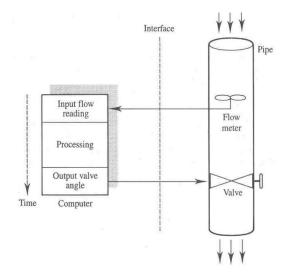

Most "soft" real-time tasks should finish before their deadlines.

e.g. frame rate in a videoconf. should be kept above 15fps most of the time

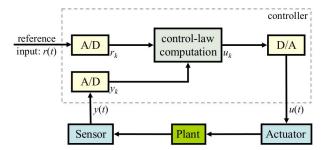

Many real-time systems combine "hard" and "soft" real-time tasks.

i.e. we optimize performance w.r.t. "soft" real-time tasks under the constraint that "hard" real-time tasks are finished before their deadlines

- Digital process control
 - anti-lock braking system
- Higher-level command and control
 - helicopter flight control
- Real-time databases
 - Stock trading systems

Computer controls the flow in the pipe in real-time

The controller (computer) controls the plant using the actuator (valve) based on sampled data from the sensor (flow meter)

- ▶ y(t) the measured state of the plant
- r(t) the desired state of the plant
- Calculate control output u(t) as a function of y(t), r(t)e.g. $u_k = u_{k-2} + \alpha(r_k - y_k) + \beta(r_{k-1} - y_{k-1}) + \gamma(r_{k-2} - y_{k-2})$ where α, β, γ are suitable constants

Pseudo-code for the controller:

set timer to interrupt periodically with period *T* foreach timer interrupt do analogue-to-digital conversion of y(t) to get y_k compute control output u_k based on r_k and y_k digital-to-analogue conversion of u_k to get u(t)end

Pseudo-code for the controller:

set timer to interrupt periodically with period *T* foreach timer interrupt do analogue-to-digital conversion of y(t) to get y_k compute control output u_k based on r_k and y_k digital-to-analogue conversion of u_k to get u(t)end

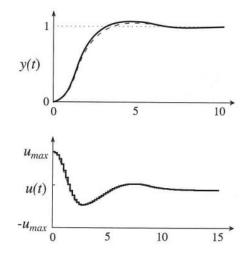

- Effective control of the plant depends on:
 - The correct reference input and control law computation
 - The accuracy of the sensor measurements
 - Resolution of the sampled data (i.e. bits per sample)
 - Frequency of interrupts (i.e. 1/T)

Pseudo-code for the controller:

set timer to interrupt periodically with period *T* foreach timer interrupt do analogue-to-digital conversion of y(t) to get y_k compute control output u_k based on r_k and y_k digital-to-analogue conversion of u_k to get u(t)end

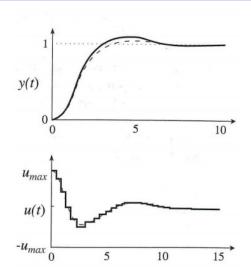

- Effective control of the plant depends on:
 - The correct reference input and control law computation
 - The accuracy of the sensor measurements
 - Resolution of the sampled data (i.e. bits per sample)
 - Frequency of interrupts (i.e. 1/T)
- T is the sampling period
 - Small T better approximates the analogue behavior
 - Large T means less processor-time demand
 - ... but may result in unstable control

Example

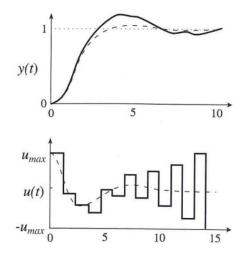

r(t) = 1 for $t \ge 0$

Example

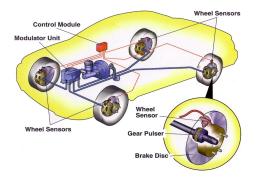

r(t) = 1 for $t \ge 0$

Example

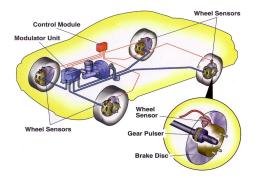

r(t) = 1 for $t \ge 0$

Anti-Lock Braking System

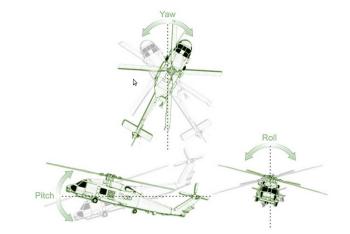

The controller monitors the speed sensors in wheels Right before a wheel locks up, it experiences a rapid deceleration

Anti-Lock Braking System

- The controller monitors the speed sensors in wheels Right before a wheel locks up, it experiences a rapid deceleration
- If a rapid deceleration of a wheel is observed, the controller alternately
 - reduces pressure on the corresponding brake until acceleration is observed
 - then applies brake until deceleration is observed

There are also three velocity components

Two control loops: pilot's control (30Hz) and stabilization (90Hz)

Do the following in each 1/180-second cycle:

> Validate sensor data; in the presence of failures, reconfigure the system

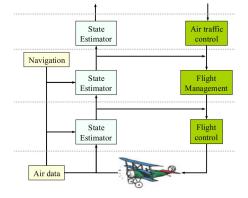

- Validate sensor data; in the presence of failures, reconfigure the system
- ► Do the following 30-Hz avionics tasks, each one every six cycles:
 - keyboard input and mode selection
 - data normalization and coordinate transformation
 - tracking reference update

- Validate sensor data; in the presence of failures, reconfigure the system
- ▶ Do the following 30-Hz avionics tasks, each one every six cycles:
 - keyboard input and mode selection
 - data normalization and coordinate transformation
 - tracking reference update
- Do the following 30-Hz avionics tasks, each one every six cycles:
 - control laws of the outer pitch-control loop
 - control laws of the outer roll-control loop
 - control laws of the outer yaw- and collective-control loop

- Validate sensor data; in the presence of failures, reconfigure the system
- ▶ Do the following 30-Hz avionics tasks, each one every six cycles:
 - keyboard input and mode selection
 - data normalization and coordinate transformation
 - tracking reference update
- Do the following 30-Hz avionics tasks, each one every six cycles:
 - control laws of the outer pitch-control loop
 - control laws of the outer roll-control loop
 - control laws of the outer yaw- and collective-control loop
- Do each of the following 90-Hz computations once every two cycles, using outputs produced by 30-Hz computations and avionics tasks:
 - control laws of the inner pitch-control loop
 - control laws of the inner roll- and collective-control loop
- Compute the control laws of the inner yaw-control loop, using outputs produced by 90-Hz control-law computations as inputs

- Validate sensor data; in the presence of failures, reconfigure the system
- Do the following 30-Hz avionics tasks, each one every six cycles:
 - keyboard input and mode selection
 - data normalization and coordinate transformation
 - tracking reference update
- Do the following 30-Hz avionics tasks, each one every six cycles:
 - control laws of the outer pitch-control loop
 - control laws of the outer roll-control loop
 - control laws of the outer yaw- and collective-control loop
- Do each of the following 90-Hz computations once every two cycles, using outputs produced by 30-Hz computations and avionics tasks:
 - control laws of the inner pitch-control loop
 - control laws of the inner roll- and collective-control loop
- Compute the control laws of the inner yaw-control loop, using outputs produced by 90-Hz control-law computations as inputs
- Output commands
- Carry out built-in-test
- Wait until the beginning of the next cycle

Higher-Level Command and Control

Controllers organized into a hierarchy

- At the lowest level we place the digital control systems that operate on the physical environment
- Higher level controllers monitor the behavior of lower levels
- Time-scale and complexity of decision making increases as one goes up the hierarchy (from control to planning)

Real-Time Database System

 Databases that contain perishable data, i.e. relevance of data deteriorates with time

Air traffic control, stock price quotation systems, tracking systems, etc.

Real-Time Database System

 Databases that contain perishable data, i.e. relevance of data deteriorates with time

Air traffic control, stock price quotation systems, tracking systems, etc.

The temporal quality of data is quantified by age of an image object, i.e. the length of time since last update

Real-Time Database System

 Databases that contain perishable data, i.e. relevance of data deteriorates with time

Air traffic control, stock price quotation systems, tracking systems, etc.

- The temporal quality of data is quantified by age of an image object, i.e. the length of time since last update
- temporal consistency
 - absolute = max. age is bounded by a fixed threshold
 - relative = max. difference in ages is bounded by a threshold e.g. planning system correlating traffic density and flow of vehicles

Applications	Size	Ave. Resp. Time	Max Resp. Time	Abs. Cons.	Rel. Cons.
Air traffic control	20,000	0.50 ms	5.00 ms	3.00 sec.	6.00 sec.
Aircraft mission	3,000	0.05 ms	1.00 ms	0.05 sec.	0.20 sec.
Spacecraft control	5,000	0.05 ms	1.00 ms	0.20 sec.	1.00 sec.
Process control		0.80 ms	5.00 sec	1.00 sec.	2.00 sec

Users of database compete for access – various models for trading consistency with time demands exist.

A system for selling/buying stock at public prices

- A system for selling/buying stock at public prices
- Prices are volatile in their movement

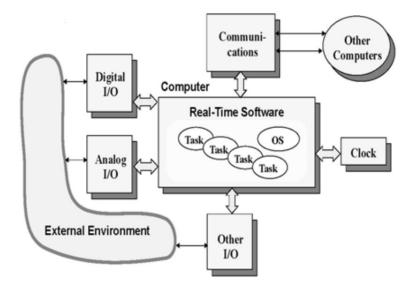

- A system for selling/buying stock at public prices
- Prices are volatile in their movement
- Stop orders:
 - set upper limit on prices for buying buy for the best available price once the limit is reached
 e.g. stock currently trading at \$30 should be bought when the price rises above \$35

- A system for selling/buying stock at public prices
- Prices are volatile in their movement
- Stop orders:
 - set upper limit on prices for buying buy for the best available price once the limit is reached e.g. stock currently trading at \$30 should be bought when the price rises above \$35
 - set lower limit on prices for selling sell for the best available price once the limit is reached
 e.g. stock currently trading at \$30 should be sold when the price sinks below \$25

- A system for selling/buying stock at public prices
- Prices are volatile in their movement
- Stop orders:
 - set upper limit on prices for buying buy for the best available price once the limit is reached e.g. stock currently trading at \$30 should be bought when the price rises above \$35
 - set lower limit on prices for selling sell for the best available price once the limit is reached
 e.g. stock currently trading at \$30 should be sold when the price sinks below \$25
- Depending on the delay, the available price may be different from the limit

successful stop orders depend on the timely delivery of stock trade data and the ability to trade on the changing prices in a timely manner

Structure of Real-Time (Embedded) Applications

Types of Real-Time Systems

- Purely cyclic
 - every task executes periodically; I/O operations are polled; demands in resources do not vary
 - e.g. digital controllers

- Purely cyclic
 - every task executes periodically; I/O operations are polled; demands in resources do not vary
 - e.g. digital controllers
- Mostly cyclic
 - most tasks execute periodically; system also responds to external events (fault recovery and external commands) asynchronously
 - e.g. avionics

- Purely cyclic
 - every task executes periodically; I/O operations are polled; demands in resources do not vary
 - e.g. digital controllers
- Mostly cyclic
 - most tasks execute periodically; system also responds to external events (fault recovery and external commands) asynchronously

e.g. avionics

- Asynchronous and somewhat predictable
 - durations between consecutive executions of a task as well as demands in resources may vary considerably. These variations have either bounded range, or known statistics.

e.g. radar signal processing, tracking

- The type of application affects how we schedule tasks and prove correctness
- It is easier to reason about applications that are more cyclic, synchronous and predictable
 - Many real-time systems are designed in this manner
 - Safe, conservative, design approach, if it works

- AT&T long distance calls
- Therac-25 medical accelerator disaster
- Patriot missile mistiming

114 computer-operated electronic switches scattered across USA Handling up to 700,000 calls an hour

114 computer-operated electronic switches scattered across USA Handling up to 700,000 calls an hour

The problem:

the switch in New York City neared its load limit

114 computer-operated electronic switches scattered across USA Handling up to 700,000 calls an hour

- the switch in New York City neared its load limit
- entered a four-second maintenance reset

114 computer-operated electronic switches scattered across USA Handling up to 700,000 calls an hour

- the switch in New York City neared its load limit
- entered a four-second maintenance reset
- sent "do not disturb" to neighbors

114 computer-operated electronic switches scattered across USA Handling up to 700,000 calls an hour

- the switch in New York City neared its load limit
- entered a four-second maintenance reset
- sent "do not disturb" to neighbors
- after the reset, the switch began to distribute calls (quickly)

114 computer-operated electronic switches scattered across USA Handling up to 700,000 calls an hour

- the switch in New York City neared its load limit
- entered a four-second maintenance reset
- sent "do not disturb" to neighbors
- after the reset, the switch began to distribute calls (quickly)
- then another switch received one of these calls from New York

114 computer-operated electronic switches scattered across USA Handling up to 700,000 calls an hour

- the switch in New York City neared its load limit
- entered a four-second maintenance reset
- sent "do not disturb" to neighbors
- after the reset, the switch began to distribute calls (quickly)
- then another switch received one of these calls from New York
- began to update its records that New York was back on line

114 computer-operated electronic switches scattered across USA Handling up to 700,000 calls an hour

- the switch in New York City neared its load limit
- entered a four-second maintenance reset
- sent "do not disturb" to neighbors
- after the reset, the switch began to distribute calls (quickly)
- then another switch received one of these calls from New York
- began to update its records that New York was back on line
- a second call from New York arrived less than 10 milliseconds after the first, i.e. while the first hadn't yet been handled; this together with a SW bug caused maintenance reset

114 computer-operated electronic switches scattered across USA Handling up to 700,000 calls an hour

- the switch in New York City neared its load limit
- entered a four-second maintenance reset
- sent "do not disturb" to neighbors
- after the reset, the switch began to distribute calls (quickly)
- then another switch received one of these calls from New York
- began to update its records that New York was back on line
- a second call from New York arrived less than 10 milliseconds after the first, i.e. while the first hadn't yet been handled; this together with a SW bug caused maintenance reset
- the error was propagated further

114 computer-operated electronic switches scattered across USA Handling up to 700,000 calls an hour

The problem:

- the switch in New York City neared its load limit
- entered a four-second maintenance reset
- sent "do not disturb" to neighbors
- after the reset, the switch began to distribute calls (quickly)
- then another switch received one of these calls from New York
- began to update its records that New York was back on line
- a second call from New York arrived less than 10 milliseconds after the first, i.e. while the first hadn't yet been handled; this together with a SW bug caused maintenance reset
- the error was propagated further

The reason for failure: The system was unable to react to closely timed messages

Therac-25 medical accelerator disaster

Therac-25 = a machine for radiotheratpy

- between 1985 and 1987 (at least) six accidents involving enormous radiation overdoses to patients
- Half of these patients died due to the overdoses

- 1. electron mode
 - electron beam (low current)
 - various levels of energy (5 to 25-MeV)
 - scanning magnets used to spread the beam to a safe concentration

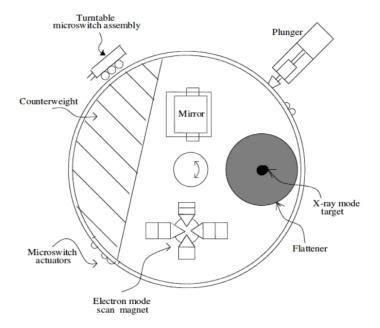

- 1. electron mode
 - electron beam (low current)
 - various levels of energy (5 to 25-MeV)
 - scanning magnets used to spread the beam to a safe concentration
- 2. photon mode
 - only one level of energy (25-MeV), much larger electron-beam current
 - electron beam strikes a metal foil to produce X-rays (photons)
 - the X-ray beam is "flattened" by a device below the foil

- 1. electron mode
 - electron beam (low current)
 - various levels of energy (5 to 25-MeV)
 - scanning magnets used to spread the beam to a safe concentration
- 2. photon mode
 - only one level of energy (25-MeV), much larger electron-beam current
 - electron beam strikes a metal foil to produce X-rays (photons)
 - the X-ray beam is "flattened" by a device below the foil
- light mode just light beam used to illuminate the field on the surface of the patient's body that will be treated

- 1. electron mode
 - electron beam (low current)
 - various levels of energy (5 to 25-MeV)
 - scanning magnets used to spread the beam to a safe concentration
- 2. photon mode
 - only one level of energy (25-MeV), much larger electron-beam current
 - electron beam strikes a metal foil to produce X-rays (photons)
 - the X-ray beam is "flattened" by a device below the foil
- light mode just light beam used to illuminate the field on the surface of the patient's body that will be treated

All devices placed on a turntable, supposed to be rotated to the correct position before the beam is started up

Therac-25 – turntable

The Software

The software responsible for

- Operator
 - Monitoring input and editing changes from an operator
 - Updating the screen to show current status of machine
 - Printing in response to an operator commands

The Software

The software responsible for

- Operator
 - Monitoring input and editing changes from an operator
 - Updating the screen to show current status of machine
 - Printing in response to an operator commands
- Machine
 - monitoring the machine status
 - placement of turntable
 - strength and shape of beam
 - operation of bending and scanning magnets
 - setting the machine up for the specified treatment
 - turning the beam on
 - turning the beam off (after treatment, on operator command, or if a malfunction is detected)

The Software

The software responsible for

- Operator
 - Monitoring input and editing changes from an operator
 - Updating the screen to show current status of machine
 - Printing in response to an operator commands
- Machine
 - monitoring the machine status
 - placement of turntable
 - strength and shape of beam
 - operation of bending and scanning magnets
 - setting the machine up for the specified treatment
 - turning the beam on
 - turning the beam off (after treatment, on operator command, or if a malfunction is detected)

Software running several safety critical tasks in parallel! Insufficient hardware protection (as opposed to previous models)!!

The Therac-25 runs on a real-time operating system

- The Therac-25 runs on a real-time operating system
- Four major components of software: stored data, a scheduler, a set of tasks, and interrupt services (e.g. the computer clock and handling of computer-hardware-generated errors)

- The Therac-25 runs on a real-time operating system
- Four major components of software: stored data, a scheduler, a set of tasks, and interrupt services (e.g. the computer clock and handling of computer-hardware-generated errors)
- The software segregated the tasks above into
 - critical tasks: e.g. setup and operation of the beam
 - non-critical tasks: e.g. monitoring the keyboard

- The Therac-25 runs on a real-time operating system
- Four major components of software: stored data, a scheduler, a set of tasks, and interrupt services (e.g. the computer clock and handling of computer-hardware-generated errors)
- The software segregated the tasks above into
 - critical tasks: e.g. setup and operation of the beam
 - non-critical tasks: e.g. monitoring the keyboard
- The scheduler directs all non-interrupt events and orders simultaneous events

- The Therac-25 runs on a real-time operating system
- Four major components of software: stored data, a scheduler, a set of tasks, and interrupt services (e.g. the computer clock and handling of computer-hardware-generated errors)
- The software segregated the tasks above into
 - critical tasks: e.g. setup and operation of the beam
 - non-critical tasks: e.g. monitoring the keyboard
- The scheduler directs all non-interrupt events and orders simultaneous events
- Every 0.1 seconds tasks are initiated and critical tasks are executed first, with non-critical tasks taking up any remaining time

- The Therac-25 runs on a real-time operating system
- Four major components of software: stored data, a scheduler, a set of tasks, and interrupt services (e.g. the computer clock and handling of computer-hardware-generated errors)
- The software segregated the tasks above into
 - critical tasks: e.g. setup and operation of the beam
 - non-critical tasks: e.g. monitoring the keyboard
- The scheduler directs all non-interrupt events and orders simultaneous events
- Every 0.1 seconds tasks are initiated and critical tasks are executed first, with non-critical tasks taking up any remaining time

Communication between tasks based on shared variables (without proper atomic test-and-set instructions)

There were several accidents due to various bugs in software

There were several accidents due to various bugs in software One of them proceeded as follows (much simplified):

the operator entered parameters for X-rays treatment

There were several accidents due to various bugs in software One of them proceeded as follows (much simplified):

- the operator entered parameters for X-rays treatment
- the machine started to set up for the treatment

There were several accidents due to various bugs in software One of them proceeded as follows (much simplified):

- the operator entered parameters for X-rays treatment
- the machine started to set up for the treatment
- the operator changed the mode from X-rays to electron (within the interval from 1s to 8s from the end of the original editing)

There were several accidents due to various bugs in software One of them proceeded as follows (much simplified):

- the operator entered parameters for X-rays treatment
- the machine started to set up for the treatment
- the operator changed the mode from X-rays to electron (within the interval from 1s to 8s from the end of the original editing)
- the patient received X-ray "treatment" with turntable in the electron position (i.e. unshielded)

There were several accidents due to various bugs in software One of them proceeded as follows (much simplified):

- the operator entered parameters for X-rays treatment
- the machine started to set up for the treatment
- the operator changed the mode from X-rays to electron (within the interval from 1s to 8s from the end of the original editing)
- the patient received X-ray "treatment" with turntable in the electron position (i.e. unshielded)

The cause:

The turntable and treatment parameters were set by different concurrent procedures HAND and DATENT, respectively.

There were several accidents due to various bugs in software One of them proceeded as follows (much simplified):

- the operator entered parameters for X-rays treatment
- the machine started to set up for the treatment
- the operator changed the mode from X-rays to electron (within the interval from 1s to 8s from the end of the original editing)
- the patient received X-ray "treatment" with turntable in the electron position (i.e. unshielded)

The cause:

- The turntable and treatment parameters were set by different concurrent procedures HAND and DATENT, respectively.
- If the change in parameters came in the "right" time, only HAND reacted to the change.

vs

Patriot – Air defense missile system

- Patriot Air defense missile system
- Failed to intercept a scud missile on February 25, 1991 at Dhahran, Saudi Arabia

(missile hit US army barracks, 28 persons killed)

- Patriot Air defense missile system
- Failed to intercept a scud missile on February 25, 1991 at Dhahran, Saudi Arabia

(missile hit US army barracks, 28 persons killed)

The problem was caused by incorrect measurement of time

- Patriot Air defense missile system
- Failed to intercept a scud missile on February 25, 1991 at Dhahran, Saudi Arabia

(missile hit US army barracks, 28 persons killed)

The problem was caused by incorrect measurement of time

- Patriot Air defense missile system
- Failed to intercept a scud missile on February 25, 1991 at Dhahran, Saudi Arabia

(missile hit US army barracks, 28 persons killed)

The problem was caused by incorrect measurement of time

Simplified principle of function:

Patriot's radar detects an airborne object

- Patriot Air defense missile system
- Failed to intercept a scud missile on February 25, 1991 at Dhahran, Saudi Arabia

(missile hit US army barracks, 28 persons killed)

The problem was caused by incorrect measurement of time

- Patriot's radar detects an airborne object
- the object is identified as a scud missile (according to speed, size, etc.)

- Patriot Air defense missile system
- Failed to intercept a scud missile on February 25, 1991 at Dhahran, Saudi Arabia

(missile hit US army barracks, 28 persons killed)

The problem was caused by incorrect measurement of time

- Patriot's radar detects an airborne object
- the object is identified as a scud missile (according to speed, size, etc.)
- the range gate computes an area in the air space where the system should next look for it

- Patriot Air defense missile system
- Failed to intercept a scud missile on February 25, 1991 at Dhahran, Saudi Arabia

(missile hit US army barracks, 28 persons killed)

The problem was caused by incorrect measurement of time

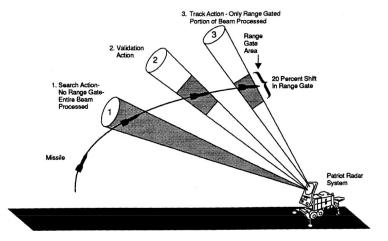

- Patriot's radar detects an airborne object
- the object is identified as a scud missile (according to speed, size, etc.)
- the range gate computes an area in the air space where the system should next look for it
- finding the object in the calculated area confirms that it is a scud

- Patriot Air defense missile system
- Failed to intercept a scud missile on February 25, 1991 at Dhahran, Saudi Arabia

(missile hit US army barracks, 28 persons killed)

The problem was caused by incorrect measurement of time

- Patriot's radar detects an airborne object
- the object is identified as a scud missile (according to speed, size, etc.)
- the range gate computes an area in the air space where the system should next look for it
- finding the object in the calculated area confirms that it is a scud
- then the scud is intercepted

Prediction of the new area:

Prediction of the new area:

a function of velocity and time of the last radar detection

Prediction of the new area:

- > a function of *velocity* and *time* of the last radar detection
- velocity represented as a real number

Prediction of the new area:

- a function of velocity and time of the last radar detection
- velocity represented as a real number
- the current time kept by incrementing whole number counter counting tenths of seconds

Prediction of the new area:

- a function of velocity and time of the last radar detection
- velocity represented as a real number
- the current time kept by incrementing whole number counter counting tenths of seconds
- computation in 24bit fixed floating point numbers

Prediction of the new area:

- a function of velocity and time of the last radar detection
- velocity represented as a real number
- the current time kept by incrementing whole number counter counting tenths of seconds
- computation in 24bit fixed floating point numbers

The time converted to 24bit real number and multiplied with 1/10 represented in 24bit (i.e. the real value of 1/10 was 0.099999905)

Prediction of the new area:

- a function of velocity and time of the last radar detection
- velocity represented as a real number
- the current time kept by incrementing whole number counter counting tenths of seconds
- computation in 24bit fixed floating point numbers

The time converted to 24bit real number and multiplied with 1/10 represented in 24bit (i.e. the real value of 1/10 was 0.099999905)

the system was already running for 100 hours, i.e. the counter value was 360000, i.e. 360000 · 0.099999905 = 35999.6568

Prediction of the new area:

- a function of velocity and time of the last radar detection
- velocity represented as a real number
- the current time kept by incrementing whole number counter counting tenths of seconds
- computation in 24bit fixed floating point numbers

The time converted to 24bit real number and multiplied with 1/10 represented in 24bit (i.e. the real value of 1/10 was 0.099999905)

- the system was already running for 100 hours, i.e. the counter value was 360000, i.e. 360000 · 0.099999905 = 35999.6568
- the error was 0.3432 seconds, which means 687 m off MACH 5 scud missile

Prediction of the new area:

- a function of velocity and time of the last radar detection
- velocity represented as a real number
- the current time kept by incrementing whole number counter counting tenths of seconds
- computation in 24bit fixed floating point numbers

The time converted to 24bit real number and multiplied with 1/10 represented in 24bit (i.e. the real value of 1/10 was 0.099999905)

- the system was already running for 100 hours, i.e. the counter value was 360000, i.e. 360000 · 0.099999905 = 35999.6568
- the error was 0.3432 seconds, which means 687 m off MACH 5 scud missile
- the problem was not only in wrong conversion but in the fact that at some points correct conversion was used (after incomplete bug fix), so the errors did not cancel out

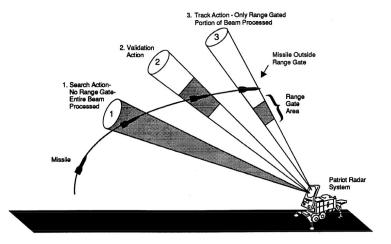

Prediction of the new area:

- a function of velocity and time of the last radar detection
- velocity represented as a real number
- the current time kept by incrementing whole number counter counting tenths of seconds
- computation in 24bit fixed floating point numbers

The time converted to 24bit real number and multiplied with 1/10 represented in 24bit (i.e. the real value of 1/10 was 0.099999905)

- the system was already running for 100 hours, i.e. the counter value was 360000, i.e. 360000 · 0.099999905 = 35999.6568
- the error was 0.3432 seconds, which means 687 m off MACH 5 scud missile
- the problem was not only in wrong conversion but in the fact that at some points correct conversion was used (after incomplete bug fix), so the errors did not cancel out

As a result, the tracking gate looked into wrong area

- Developed by Boeing & NASA
- Seven passengers, or a mix of crew and cargo, for missions to low-Earth orbit

- Developed by Boeing & NASA
- Seven passengers, or a mix of crew and cargo, for missions to low-Earth orbit

 A timing issue occured on the last Orbital Flight Test on December 20, 2019

- Developed by Boeing & NASA
- Seven passengers, or a mix of crew and cargo, for missions to low-Earth orbit

- A timing issue occured on the last Orbital Flight Test on December 20, 2019
- What is supposed to happen:
 - Atlas V leaves Starliner on a suborbital trajectory.
 - Starliner's own propulsion system takes the spacecraft into orbit and to ISS.

- Developed by Boeing & NASA
- Seven passengers, or a mix of crew and cargo, for missions to low-Earth orbit

- A timing issue occured on the last Orbital Flight Test on December 20, 2019
- What is supposed to happen:
 - Atlas V leaves Starliner on a suborbital trajectory.
 - Starliner's own propulsion system takes the spacecraft into orbit and to ISS.
- What happened:
 - Mission Elapsed Timer (MET), or clock, on Starliner was set to the wrong time and did not trigger the engines to fire correctly.
 - Other onboard systems compensated and it reached orbit, but had depleted so much fuel there was not enough to continue the journey.

Real-time scheduling

- Time and priority driven
- Resource control
- Multi-processor (a bit)

Real-time scheduling

- Time and priority driven
- Resource control
- Multi-processor (a bit)
- A little bit on programming real-time systems
 - Real-time operating systems

The Scheduling problem:

Input:

- available processors, resources
- set of tasks/jobs

with their requirements, deadlines, etc.

The Scheduling problem:

Input:

- available processors, resources
- set of tasks/jobs

with their requirements, deadlines, etc.

Question: How to assign processors and resources to tasks/jobs so that all requirements are met?

The Scheduling problem:

Input:

- available processors, resources
- set of tasks/jobs

with their requirements, deadlines, etc.

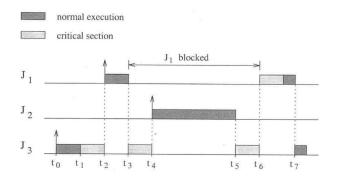

Question: How to assign processors and resources to tasks/jobs so that all requirements are met?

Example:

...

- 1 processor, one critical section shared by job 1 and job 3
- job 1: release time 1, computation time 4, deadline 8
- job 2: release time 1, computation time 2, deadline 5
- job 3: release time 0, computation time 3, deadline 4

Outline – Scheduling

- We consider a formal model of systems with parallel jobs that possibly contend for shared resources consider periodic as well as aperiodic jobs
- Consider various algorithms that schedule jobs to meet their timing constraints offline and online algorithms, RM, EDF, etc.

Outline – Programming

Basic information about RTOS and RT programming languages

- RTOS overview
 - real-time in non-real-time operating systems
 - implementation of theoretical concepts in freeRTOS

RT in programming languages – short overview

Real-Time Scheduling

Formal Model

[Some parts of this lecture are based on a real-time systems course of Colin Perkins

http://csperkins.org/teaching/rtes/index.html]

Real-Time Scheduling – Formal Model

Introduce an abstract model of real-time systems

- abstracts away unessential details
- sets up consistent terminology

Real-Time Scheduling – Formal Model

- Introduce an abstract model of real-time systems
 - abstracts away unessential details
 - sets up consistent terminology
- Three components of the model
 - A workload model that describes applications supported by the system
 - i.e. jobs, tasks, ...
 - A resource model that describes the system resources available to applications i.e. processors, passive resources, ...
 - Algorithms that define how the application uses the resources at all times
 i.e. scheduling and resource access protocols

Basic Notions

A job is a unit of work that is scheduled and executed by a system

compute a control law, transform sensor data, etc.

Basic Notions

A job is a unit of work that is scheduled and executed by a system compute a control law, transform sensor data, etc.

A task is a set of related jobs which jointly provide some system function

check temperature periodically, keep a steady flow of water

A job is a unit of work that is scheduled and executed by a system compute a control law, transform sensor data, etc.

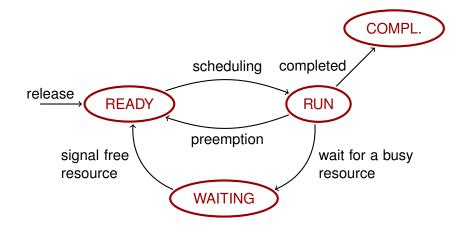

- A task is a set of related jobs which jointly provide some system function check temperature periodically, keep a steady flow of water
- A job executes on a processor
 CPU, transmission link in a network, database server, etc.

A job is a unit of work that is scheduled and executed by a system compute a control law, transform sensor data, etc.

A task is a set of related jobs which jointly provide some system function check temperature periodically, keep a steady flow of water

- A job executes on a processor
 CPU, transmission link in a network, database server, etc.
- A job may use some (shared) passive resources file, database lock, shared variable etc.

Life Cycle of a Job

We consider finite, or countably infinite number of jobs J_1, J_2, \ldots

Each job has several parameters.

We consider finite, or countably infinite number of jobs $J_1, J_2, ...$

Each job has several parameters.

There are four types of job parameters:

- temporal
 - release time, execution time, deadlines
- functional
 - Laxity type: hard and soft real-time
 - preemptability, (criticality)
- interconnection
 - precedence constraints
- resource

usage of processors and passive resources

Execution time e_i of a job J_i – the amount of time required to complete the execution of J_i when it executes alone and has all necessary resources

Execution time e_i of a job J_i – the amount of time required to complete the execution of J_i when it executes alone and has all necessary resources

- Value of e_i depends upon complexity of the job and speed of the processor on which it executes; may change for various reasons:
 - Conditional branches
 - Caches, pipelines, etc.
 - ...
- Execution times fall into an interval [e_i⁻, e_i⁺]; we assume that we know this interval (WCET analysis) but not necessarily e_i

Execution time e_i of a job J_i – the amount of time required to complete the execution of J_i when it executes alone and has all necessary resources

- Value of e_i depends upon complexity of the job and speed of the processor on which it executes; may change for various reasons:
 - Conditional branches
 - Caches, pipelines, etc.

▶ ...

Execution times fall into an interval [e_i⁻, e_i⁺]; we assume that we know this interval (WCET analysis) but not necessarily e_i

We usually validate the system using only e_i^+ for each job i.e. assume $e_i = e_i^+$

Job Parameters – Release and Response Time

Release time r_i – the instant in time when a job J_i becomes available for execution

- ▶ Release time may *jitter*, only an interval $[r_i^-, r_i^+]$ is known
- A job can be executed at any time at, or after, its release time, provided its processor and resource demands are met

Job Parameters – Release and Response Time

Release time r_i – the instant in time when a job J_i becomes available for execution

- ▶ Release time may *jitter*, only an interval $[r_i^-, r_i^+]$ is known
- A job can be executed at any time at, or after, its release time, provided its processor and resource demands are met

Completion time C_i – the instant in time when a job completes its execution

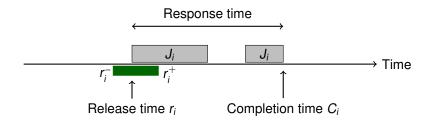

Job Parameters – Release and Response Time

Release time r_i – the instant in time when a job J_i becomes available for execution

- ▶ Release time may *jitter*, only an interval $[r_i^-, r_i^+]$ is known
- A job can be executed at any time at, or after, its release time, provided its processor and resource demands are met

Completion time C_i – the instant in time when a job completes its execution

Response time – the difference $C_i - r_i$ between the completion time and the release time

Job Parameters – Deadlines

Absolute deadline d_i – the instant in time by which a job must be completed

Job Parameters – Deadlines

Absolute deadline d_i – the instant in time by which a job must be completed

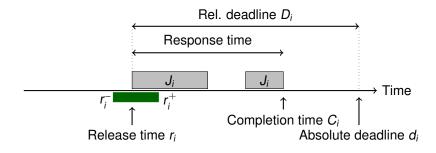

Relative deadline D_i – the maximum allowable response time i.e. $D_i = d_i - r_i$

Job Parameters – Deadlines

Absolute deadline d_i – the instant in time by which a job must be completed

Relative deadline D_i – the maximum allowable response time i.e. $D_i = d_i - r_i$

Feasible interval is the interval (*r_i*, *d_i*]

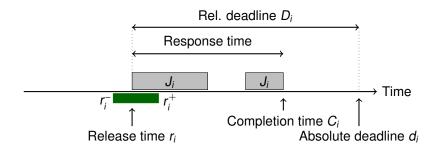

Job Parameters – Deadlines

Absolute deadline d_i – the instant in time by which a job must be completed

Relative deadline D_i – the maximum allowable response time i.e. $D_i = d_i - r_i$

Feasible interval is the interval (*r_i*, *d_i*]

A *timing constraint* of a job is specified using release time together with relative and absolute deadlines.

A hard real-time constraint specifies that a job should never miss its deadline.

Examples: Flight control, railway signaling, anti-lock brakes, etc.

A hard real-time constraint specifies that a job should never miss its deadline.

Examples: Flight control, railway signaling, anti-lock brakes, etc.

Several more precise definitions occur in literature:

A timing constraint is hard if the failure to meet it is considered a fatal error

e.g. a bomb is dropped too late and hits civilians

A hard real-time constraint specifies that a job should never miss its deadline.

Examples: Flight control, railway signaling, anti-lock brakes, etc.

Several more precise definitions occur in literature:

A timing constraint is hard if the failure to meet it is considered a fatal error

e.g. a bomb is dropped too late and hits civilians

A timing constraint is hard if the usefulness of the results falls off abruptly (may even become negative) at the deadline Here the nature of abruptness allows to soften the constraint

A hard real-time constraint specifies that a job should never miss its deadline.

Examples: Flight control, railway signaling, anti-lock brakes, etc.

Several more precise definitions occur in literature:

A timing constraint is hard if the failure to meet it is considered a fatal error

e.g. a bomb is dropped too late and hits civilians

A timing constraint is hard if the usefulness of the results falls off abruptly (may even become negative) at the deadline Here the nature of abruptness allows to soften the constraint

Definition 5

A *timing constraint is hard* if the user requires *formal validation* that the job meets its timing constraint.

A **soft real-time constraint** specifies that a job could occasionally miss its deadline

Examples: stock trading, multimedia, etc.

A **soft real-time constraint** specifies that a job could occasionally miss its deadline

Examples: stock trading, multimedia, etc.

Several more precise definitions occur in literature:

A timing constraint is soft if the failure to meet it is undesirable but acceptable if the probability is low

A **soft real-time constraint** specifies that a job could occasionally miss its deadline

Examples: stock trading, multimedia, etc.

Several more precise definitions occur in literature:

- A timing constraint is soft if the failure to meet it is undesirable but acceptable if the probability is low
- A timing constraint is soft if the usefulness of the results decreases at a slower rate with *tardiness* of the job

e.g. the probability that a response time exceeds 50 ms is less than 0.2

A **soft real-time constraint** specifies that a job could occasionally miss its deadline

Examples: stock trading, multimedia, etc.

Several more precise definitions occur in literature:

- A timing constraint is soft if the failure to meet it is undesirable but acceptable if the probability is low
- A timing constraint is soft if the usefulness of the results decreases at a slower rate with *tardiness* of the job

e.g. the probability that a response time exceeds 50 ms is less than 0.2

Definition 6

A *timing constraint is soft* if either validation is not required, or only a demonstration that a *statistical constraint* is met suffices.

Jobs – Preemptability

Jobs may be interrupted by higher priority jobs

Jobs may be interrupted by higher priority jobs

- A job is preemptable if its execution can be interrupted
- A job is non-preemptable if it must run to completion once started

(Some preemptable jobs have periods during which they cannot be preempted)

The context switch time is the time to switch between jobs (Most of the time we assume that this time is negligible) Jobs may be interrupted by higher priority jobs

- A job is preemptable if its execution can be interrupted
- A job is non-preemptable if it must run to completion once started

(Some preemptable jobs have periods during which they cannot be preempted)

The context switch time is the time to switch between jobs (Most of the time we assume that this time is negligible)

Reasons for preemptability:

- Jobs may have different levels of criticality e.g. brakes vs radio tunning
- Priorities may make part of scheduling algorithm e.g. resource access control algorithms

Jobs – Precedence Constraints

Jobs may be constrained to execute in a particular order

Jobs – Precedence Constraints

Jobs may be constrained to execute in a particular order

- This is known as a precedence constraint
- A job J_i is a predecessor of another job J_k and J_k a successor of J_i (denoted by J_i < J_k) if J_k cannot begin execution until the execution of J_i completes
- ► J_i is an *immediate predecessor* of J_k if J_i < J_k and there is no other job J_j such that J_i < J_j < J_k
- ► J_i and J_k are *independent* when neither $J_i < J_k$ nor $J_k < J_i$

Jobs – Precedence Constraints

Jobs may be constrained to execute in a particular order

- This is known as a precedence constraint
- A job J_i is a predecessor of another job J_k and J_k a successor of J_i (denoted by J_i < J_k) if J_k cannot begin execution until the execution of J_i completes
- ► J_i is an *immediate predecessor* of J_k if J_i < J_k and there is no other job J_j such that J_i < J_j < J_k
- ► J_i and J_k are *independent* when neither $J_i < J_k$ nor $J_k < J_i$

A job with a precedence constraint becomes ready for execution when its release time has passed and when all predecessors have completed.

Example: authentication before retrieving an information, a signal processing job in radar surveillance system precedes a tracker job

Tasks – Modeling Reactive Systems

Reactive systems - run for unlimited amount of time

Tasks – Modeling Reactive Systems

Reactive systems - run for unlimited amount of time

A system parameter: number of tasks

- may be known in advance (flight control)
- may change during computation (air traffic control)

Tasks – Modeling Reactive Systems

Reactive systems – run for unlimited amount of time

A system parameter: number of tasks

- may be known in advance (flight control)
- may change during computation (air traffic control)

We consider three types of tasks

- Periodic jobs executed at regular intervals, hard deadlines
- Aperiodic jobs executed in random intervals, soft deadlines
- Sporadic jobs executed in random intervals, hard deadlines

... precise definitions later.

Processors

A processor, P, is an active component on which jobs are scheduled

Processors

A processor, P, is an active component on which jobs are scheduled

The general case considered in literature:

m processors P_1, \ldots, P_m , each P_i has its type and speed.

A processor, P, is an active component on which jobs are scheduled

The general case considered in literature:

m processors P_1, \ldots, P_m , each P_i has its *type* and *speed*.

We mostly concentrate on single processor scheduling

- Efficient scheduling algorithms
- In a sense subsumes multiprocessor scheduling where tasks are assigned statically to individual processors

i.e. all jobs of every task are assigned to a single processor

A processor, P, is an active component on which jobs are scheduled

The general case considered in literature:

m processors P_1, \ldots, P_m , each P_i has its *type* and *speed*.

We mostly concentrate on single processor scheduling

- Efficient scheduling algorithms
- In a sense subsumes multiprocessor scheduling where tasks are assigned statically to individual processors

i.e. all jobs of every task are assigned to a single processor

Multi-processor scheduling is a rich area of current research, we touch it only lightly (later).

A resource, R, is a passive entity upon which jobs may depend

A resource, *R*, is a *passive* entity upon which jobs may depend In general, we consider *n* resources R_1, \ldots, R_n of distinct types

A resource, R, is a *passive* entity upon which jobs may depend In general, we consider *n* resources R_1, \ldots, R_n of distinct types Each R_i is used in a mutually exclusive manner

- A job that acquires a free resource locks the resource
- Jobs that need a busy resource have to wait until the resource is released
- Once released, the resource may be used by another job (i.e. it is not consumed)

(More generally, each resource may be used by k jobs concurrently, i.e., there are k units of the resource)

A resource, R, is a *passive* entity upon which jobs may depend In general, **we consider** *n* **resources** R_1, \ldots, R_n **of distinct types** Each R_i is used in a mutually exclusive manner

- A job that acquires a free resource locks the resource
- Jobs that need a busy resource have to wait until the resource is released
- Once released, the resource may be used by another job (i.e. it is not consumed)

(More generally, each resource may be used by k jobs concurrently, i.e., there are k units of the resource)

Resource requirements of a job specify

- which resources are used by the job
- the time interval(s) during which each resource is required (precise definitions later)

Schedule assigns, in every time instant, processors and resources to jobs.

More formally, a schedule is a function

$$\sigma: \{J_1,\ldots\}\times\mathbb{R}^+_0\to\mathcal{P}(\{P_1,\ldots,P_m,R_1,\ldots,R_n\})$$

so that for every $t \in \mathbb{R}_0^+$ there are rational $0 \le t_1 \le t < t_2$ such that $\sigma(J_i, \cdot)$ is constant on $[t_1, t_2)$.

(We also assume that there is the least time quantum in which scheduler does not change its decisions, i.e. each of the intervals $[t_1, t_2)$ is larger than a fixed $\varepsilon > 0$.)

Valid and Feasible Schedule

A schedule is *valid* if it satisfies the following conditions:

- Every processor is assigned to at most one job at any time
- Every job is assigned to at most one processor at any time
- No job is scheduled before its release time
- The total amount of processor time assigned to a given job is equal to its actual execution time
- All the precedence and resource usage constraints are satisfied

Valid and Feasible Schedule

A schedule is *valid* if it satisfies the following conditions:

- Every processor is assigned to at most one job at any time
- Every job is assigned to at most one processor at any time
- No job is scheduled before its release time
- The total amount of processor time assigned to a given job is equal to its actual execution time
- All the precedence and resource usage constraints are satisfied

A schedule is *feasible* if *all jobs with hard real-time constraints* complete before their deadlines

A schedule is *valid* if it satisfies the following conditions:

- Every processor is assigned to at most one job at any time
- Every job is assigned to at most one processor at any time
- No job is scheduled before its release time
- The total amount of processor time assigned to a given job is equal to its actual execution time
- All the precedence and resource usage constraints are satisfied

A schedule is *feasible* if *all jobs with hard real-time constraints* complete before their deadlines

A set of jobs is *schedulable* if there is a feasible schedule for the set.

Scheduling algorithm computes a schedule for a set of jobs A set of jobs is *schedulable according to a scheduling algorithm* if the algorithm produces a feasible schedule Scheduling algorithm computes a schedule for a set of jobs A set of jobs is *schedulable according to a scheduling algorithm* if the algorithm produces a feasible schedule Scheduling algorithm computes a schedule for a set of jobs A set of jobs is *schedulable according to a scheduling algorithm* if the algorithm produces a feasible schedule

Definition 7

A scheduling algorithm is optimal if it always produces a feasible schedule whenever such a schedule exists.

Real-Time Scheduling

Individual Jobs

Scheduling of Individual Jobs

We start with scheduling of finite sets of jobs $\{J_1, \ldots, J_m\}$ for execution on **single processor** systems.

Scheduling of Individual Jobs

We start with scheduling of finite sets of jobs $\{J_1, \ldots, J_m\}$ for execution on **single processor** systems.

Each J_i has a release time r_i , an execution time e_i and an absolute deadline d_i .

We assume hard real-time constraints.

The question: Is there an optimal scheduling algorithm?

Scheduling of Individual Jobs

We start with scheduling of finite sets of jobs $\{J_1, \ldots, J_m\}$ for execution on **single processor** systems.

Each J_i has a release time r_i , an execution time e_i and an absolute deadline d_i .

We assume hard real-time constraints.

The question: Is there an optimal scheduling algorithm? We proceed in the direction of growing generality:

- **1.** No resources, independent, synchronized (i.e. $r_i = 0$ for all *i*)
- 2. No resources, independent but not synchronized
- 3. No resources but possibly dependent
- 4. The general case

	J_1	J ₂	J_3	J_4	J_5
ei	1	1	1	3	2
di	3	10	7	8	5

Is there a feasible schedule?

	J_1	J ₂	J_3	J_4	J_5
ei	1	1	1	3	2
di	3	10	7	8	5

Is there a feasible schedule?

Note: Preemption does not help in synchronized case.

	J_1	J ₂	J_3	J_4	J_5
ei	1	1	1	3	2
di	3	10	7	8	5

Is there a feasible schedule?

Note: Preemption does not help in synchronized case.

Theorem 8

If there are no resource contentions, then executing independent jobs in the order of non-decreasing deadline (EDD) produces a feasible schedule (if it exists).

	J_1	J ₂	J_3	J_4	J_5
ei	1	1	1	3	2
di	3	10	7	8	5

Is there a feasible schedule?

Note: Preemption does not help in synchronized case.

Theorem 8

If there are no resource contentions, then executing independent jobs in the order of non-decreasing deadline (EDD) produces a feasible schedule (if it exists).

Proof.

Let σ be a schedule. **Inversion** is a pair (J_a , J_b) such that J_a precedes J_b in σ but $d_b < d_a$.

Note that σ is EDD iff it does not contain any inversion.

Assume k > 0 inversions in σ .

Let (J_a, J_b) be an inversion such that J_a is scheduled right before J_b . There is always at least one such inversion (homework).

Let $t_a < t_b$ be the time instants when J_a , J_b start to be executed in σ . Recall: C_a , C_b are completion times of J_a , J_b , and e_a , e_b are execution times. Note that $C_a \le d_a$ and that $C_b \le d_b < d_a$.

Assume k > 0 inversions in σ .

Let (J_a, J_b) be an inversion such that J_a is scheduled right before J_b . There is always at least one such inversion (homework).

Let $t_a < t_b$ be the time instants when J_a , J_b start to be executed in σ . Recall: C_a , C_b are completion times of J_a , J_b , and e_a , e_b are execution times. Note that $C_a \leq d_a$ and that $C_b \leq d_b < d_a$.

Define a new schedule σ' in which:

- All jobs except J_a , J_b are scheduled as in σ ,
- J_b starts at t_a ,
- J_a starts at $t_a + e_b$.

Observe that σ' is still feasible:

- ► J_b is completed at $t_a + e_b < t_a + e_b + e_a = t_b + e_b = C_b \le d_b$
- J_a is completed at $t_a + e_b + e_a = C_b \le d_b < d_a$

Note that σ' has k - 1 inversions. By repeating the above procedure k times, we obtain an EDD schedule.

Is there any simple schedulability test?

 $\{J_1, \ldots, J_n\}$ where $d_1 \leq \cdots \leq d_n$ is schedulable iff $\forall i \in \{1, \ldots, n\}$: $\sum_{k=1}^{i} e_k \leq d_i$

	J_1	J_2	J_3
ri	0	0	2
ei	1	2	2
di	2	5	4

- find a (feasible) schedule (with and without preemption)
- determine response time of each job in your schedule

	J_1	J_2	J_3
ri	0	0	2
ei	1	2	2
di	2	5	4

- find a (feasible) schedule (with and without preemption)
- determine response time of each job in your schedule

Preemption makes a difference.

Earliest Deadline First (EDF) scheduling:

At any time instant, a job with the earliest absolute deadline is executed

Here EDF works in the preemptive case but not in the non-preemptive one.

	J_1	J ₂
r _i	0	1
ei	4	2
di	7	5

Theorem 9

If there are no resource contentions, jobs are independent and preemption is allowed, the EDF algorithm finds a feasible schedule (if it exists).

Proof.

We show that any feasible schedule σ can be transformed in finitely many steps to EDF schedule which is feasible.

Theorem 9

If there are no resource contentions, jobs are independent and preemption is allowed, the EDF algorithm finds a feasible schedule (if it exists).

Proof.

We show that any feasible schedule σ can be transformed in finitely many steps to EDF schedule which is feasible.

Let σ be a feasible schedule but not EDF. Assume, w.l.o.g., that for every $k \in \mathbb{N}$ at most one job is executed in the interval [k, k + 1) and that all release times and deadlines are in \mathbb{N} .

(Otherwise rescale by the least common multiple.)

We say that σ violates EDF at *k* if one of the following conditions holds:

- 1. No job is executed in [k, k + 1) and there is a job J_b ready for execution in [k, k + 1)
- **2.** There are two jobs J_a and J_b that satisfy:
 - J_a and J_b are ready for execution at k
 - J_a is executed in [k, k + 1)
 - $d_b < d_a$

We say that σ violates EDF at *k* if one of the following conditions holds:

- 1. No job is executed in [k, k + 1) and there is a job J_b ready for execution in [k, k + 1)
- **2.** There are two jobs J_a and J_b that satisfy:
 - J_a and J_b are ready for execution at k
 - J_a is executed in [k, k + 1)
 - $d_b < d_a$

Let $k \in \mathbb{N}$ be the *least* time instant such that σ violates EDF at k.

Assume, w.l.o.g. that J_b has the minimum deadline among all jobs ready for execution at k.

Consider the above two cases separately:

- ad 1. Let us define a new schedule σ' which is the same as σ except that J_b is executed in the empty interval [k, k + 1).
- ad 2. There is $k < \ell < d_b$ such that J_b is executed in $[\ell, \ell + 1)$. Let us define a new schedule σ' which is the same as σ except:
 - executes J_b in [k, k + 1)
 - executes J_a in $[\ell, \ell+1)$

In both cases the σ' is feasible and does not violate EDF at any $k' \leq k$.

Finitely many steps transform any feasible schedule to EDF.

The **non-preemptive** case is NP-hard.

The **non-preemptive** case is NP-hard.

Heuristics are needed, such as the **Spring algorithm**, that usually work in much more general setting (with resources etc.)

The **non-preemptive** case is NP-hard.

Heuristics are needed, such as the **Spring algorithm**, that usually work in much more general setting (with resources etc.)

Use the notion of *partial schedule* where only a subset of jobs has been scheduled.

Exhaustive search through partial schedules

start with an empty schedule

The **non-preemptive** case is NP-hard.

Heuristics are needed, such as the **Spring algorithm**, that usually work in much more general setting (with resources etc.)

Use the notion of *partial schedule* where only a subset of jobs has been scheduled.

Exhaustive search through partial schedules

- start with an empty schedule
- in every step either
 - add a job which maximizes a *heuristic function H* among jobs that have not yet been tried in this partial schedule
 - or backtrack if there is no such a job

The **non-preemptive** case is NP-hard.

Heuristics are needed, such as the **Spring algorithm**, that usually work in much more general setting (with resources etc.)

Use the notion of *partial schedule* where only a subset of jobs has been scheduled.

Exhaustive search through partial schedules

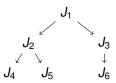

- start with an empty schedule
- in every step either
 - add a job which maximizes a *heuristic function H* among jobs that have not yet been tried in this partial schedule
 - or backtrack if there is no such a job
- After failure, backtrack to previous partial schedule

Heuristic function identifies plausible jobs to be scheduled (earliest release, earliest deadline, etc.)

Example:

ſ		J_1	J ₂	J_3	J_4	J_5	J_6
ſ	ei	1	1	1	1	1	1
	di	2	5	4	3	5	6

Dependencies:

Does EDF work?

Theorem 10

Assume that there are no resource contentions and jobs are preemptable. There is a polynomial time algorithm which decides whether a feasible schedule exists and if yes, then computes one.

Idea: Reduce to independent jobs by changing release times and deadlines. Then use EDF.

Theorem 10

Assume that there are no resource contentions and jobs are preemptable. There is a polynomial time algorithm which decides whether a feasible schedule exists and if yes, then computes one.

Idea: Reduce to independent jobs by changing release times and deadlines. Then use EDF.

Observe that if $J_i < J_k$ then replacing

• r_k with max{ $r_k, r_i + e_i$ }

 $(J_k$ cannot be scheduled for execution before $r_i + e_i$ because J_i cannot be finished before $r_i + e_i$)

• d_i with min{ d_i , $d_k - e_k$ } (J_i must be finished before $d_k - e_k$ so that J_k can be finished before d_k)

does not change feasibility.

Replace systematically according to the precedence relation.

Define r_k^*, d_k^* systematically as follows:

- Pick J_k whose all predecessors have been processed and compute r^{*}_k := max{r_k, max_{Ji<Jk} r^{*}_i + e_i}. Repeat for all jobs.
- ▶ Pick J_k whose all successors have been processed and compute d^{*}_k := min{d_k, min_{J_k<J_i} d^{*}_i e_i}. Repeat for all jobs.

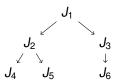

Define r_k^* , d_k^* systematically as follows:

- Pick J_k whose all predecessors have been processed and compute r^{*}_k := max{r_k, max_{Ji<Jk} r^{*}_i + e_i}. Repeat for all jobs.
- ▶ Pick J_k whose all successors have been processed and compute d^{*}_k := min{d_k, min_{J_k<J_i} d^{*}_i - e_i}. Repeat for all jobs.

Example:

	J_1	J ₂	J_3	J_4	J_5	J_6
ei	1	1	1	1	1	1
di	2	5	4	3	5	6

Dependencies:

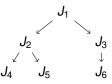

Define r_k^* , d_k^* systematically as follows:

- Pick J_k whose all predecessors have been processed and compute r^{*}_k := max{r_k, max_{Ji<Jk} r^{*}_i + e_i}. Repeat for all jobs.
- ▶ Pick J_k whose all successors have been processed and compute d^{*}_k := min{d_k, min_{J_k<J_i} d^{*}_i - e_i}. Repeat for all jobs.

Example:

	J_1	J ₂	J_3	J_4	J_5	J_6
ei	1	1	1	1	1	1
di	2	5	4	3	5	6

Dependencies:

Do you need the precedence constraints?

Define r_k^* , d_k^* systematically as follows:

- Pick J_k whose all predecessors have been processed and compute r^{*}_k := max{r_k, max_{Ji<Jk} r^{*}_i + e_i}. Repeat for all jobs.
- ▶ Pick J_k whose all successors have been processed and compute d^{*}_k := min{d_k, min_{J_k<J_i} d^{*}_i e_i}. Repeat for all jobs.

Define r_k^* , d_k^* systematically as follows:

- Pick J_k whose all predecessors have been processed and compute r^{*}_k := max{r_k, max_{Ji<Jk} r^{*}_i + e_i}. Repeat for all jobs.
- ▶ Pick J_k whose all successors have been processed and compute d^{*}_k := min{d_k, min_{J_k<J_i} d^{*}_i - e_i}. Repeat for all jobs.

This gives a new set of jobs J_1^*, \ldots, J_m^* where each J_k^* has the release time r_k^* and the absolute deadline d_k^* .

We impose **no precedence constraints** on J_1^*, \ldots, J_m^* .

Define r_k^* , d_k^* systematically as follows:

- Pick J_k whose all predecessors have been processed and compute r^{*}_k := max{r_k, max_{Ji<Jk} r^{*}_i + e_i}. Repeat for all jobs.
- ▶ Pick J_k whose all successors have been processed and compute d^{*}_k := min{d_k, min_{Jk<Ji} d^{*}_i - e_i}. Repeat for all jobs.

This gives a new set of jobs J_1^*, \ldots, J_m^* where each J_k^* has the release time r_k^* and the absolute deadline d_k^* .

We impose **no precedence constraints** on J_1^*, \ldots, J_m^* .

Lemma 11

 $\{J_1, \ldots, J_m\}$ is feasible iff $\{J_1^*, \ldots, J_m^*\}$ is feasible. If EDF schedule is feasible on $\{J_1^*, \ldots, J_m^*\}$, then the same schedule is feasible on $\{J_1, \ldots, J_m\}$.

The same schedule means that whenever J_i^* is scheduled at time t, then J_i is scheduled at time t.

Recall: $r_k^* := \max\{r_k, \max_{J_i < J_k} r_i^* + e_i\}$ and $d_k^* := \min\{d_k, \min_{J_k < J_i} d_i^* - e_i\}$

Proof of Lemma 11.

⇒: It is easy to show that in *no feasible schedule* on $\{J_1, \ldots, J_m\}$ any job J_k can be executed before r_k^* and completed after d_k^* (otherwise, precedence constraints would be violated).

Recall: $r_k^* := \max\{r_k, \max_{J_i < J_k} r_i^* + e_i\}$ and $d_k^* := \min\{d_k, \min_{J_k < J_i} d_i^* - e_i\}$

Proof of Lemma 11.

⇒: It is easy to show that in *no feasible schedule* on $\{J_1, ..., J_m\}$ any job J_k can be executed before r_k^* and completed after d_k^* (otherwise, precedence constraints would be violated).

 \Leftarrow : Assume that EDF *σ* is feasible on $\{J_1^*, \ldots, J_m^*\}$. Let us use *σ* on $\{J_1, \ldots, J_m\}$.

I.e. J_i is executed iff J_i^* is executed.

Recall: $r_k^* := \max\{r_k, \max_{J_i < J_k} r_i^* + e_i\}$ and $d_k^* := \min\{d_k, \min_{J_k < J_i} d_i^* - e_i\}$

Proof of Lemma 11.

⇒: It is easy to show that in *no feasible schedule* on $\{J_1, ..., J_m\}$ any job J_k can be executed before r_k^* and completed after d_k^* (otherwise, precedence constraints would be violated).

 \Leftarrow : Assume that EDF *σ* is feasible on $\{J_1^*, \ldots, J_m^*\}$. Let us use *σ* on $\{J_1, \ldots, J_m\}$.

I.e. J_i is executed iff J_i^* is executed.

Timing constraints of $\{J_1, \ldots, J_m\}$ are satisfied since $r_k \le r_k^*$ and $d_k \ge d_k^*$ for all k.

Recall: $r_k^* := \max\{r_k, \max_{J_i < J_k} r_i^* + e_i\}$ and $d_k^* := \min\{d_k, \min_{J_k < J_i} d_i^* - e_i\}$

Proof of Lemma 11.

⇒: It is easy to show that in *no feasible schedule* on $\{J_1, ..., J_m\}$ any job J_k can be executed before r_k^* and completed after d_k^* (otherwise, precedence constraints would be violated).

 \Leftarrow : Assume that EDF *σ* is feasible on $\{J_1^*, \ldots, J_m^*\}$. Let us use *σ* on $\{J_1, \ldots, J_m\}$.

I.e. J_i is executed iff J_i^* is executed.

Timing constraints of $\{J_1, \ldots, J_m\}$ are satisfied since $r_k \le r_k^*$ and $d_k \ge d_k^*$ for all k.

Precedence constraints: Assume that $J_s < J_t$. Then J_s^* executes completely before J_t^* since $r_s^* < r_s^* + e_s \le r_t^*$ and $d_s^* \le d_t^* - e_t < d_t^*$ and σ is EDF on $\{J_1^* \dots, J_m^*\}$.

Even the preemptive case is NP-hard

- reduce the non-preemptive case without resources to the preemptive with resources
- ► Use a common resource *R*.
 - ▶ Whenever a job starts its execution it locks the resource *R*.
 - Whenever a job finishes its execution it releases the resourse R.

Could be solved using heuristics, e.g. the Spring algorithm.

Real-Time Scheduling

Scheduling of Reactive Systems

[Some parts of this lecture are based on a real-time systems course of Colin Perkins

http://csperkins.org/teaching/rtes/index.html]

Reminder of Basic Notions

- Jobs are executed on processors and need resources
- Parameters of jobs
 - temporal:
 - release time r_i
 - execution time e_i
 - absolute deadline d_i
 - derived params: relative deadline (*D_i*), completion time, response time, ...
 - functional:
 - laxity type: hard vs soft
 - preemptability
 - interconnection
 - precedence constraints (independence)
 - resource
 - what resources and when are used by the job
- Tasks = sets of jobs

We have considered scheduling of individual jobs From this point on we concentrate on reactive systems i.e. systems that run for unlimited amount of time

We have considered scheduling of individual jobs From this point on we concentrate on reactive systems i.e. systems that run for unlimited amount of time

Recall that a task is a set of related jobs that jointly provide some system function.

We have considered scheduling of individual jobs From this point on we concentrate on reactive systems i.e. systems that run for unlimited amount of time

- We consider various types of tasks
 - Periodic
 - Aperiodic
 - Sporadic

We have considered scheduling of individual jobs From this point on we concentrate on reactive systems i.e. systems that run for unlimited amount of time

Recall that a task is a set of related jobs that jointly provide some system function.

- We consider various types of tasks
 - Periodic
 - Aperiodic
 - Sporadic
- Differ in execution time patterns for jobs in the tasks
- Must be modeled differently
 - Differing scheduling algorithms
 - Differing impact on system performance
 - Differing constraints on scheduling

Periodic Tasks

A periodic task T_i is a sequence of jobs $J_{i,1}, J_{i,2}, \ldots J_{i,n}, \ldots$ with the constant differences between release times of consecutive jobs, the constant execution times, and the constant relative deadlines of all jobs.

Periodic Tasks

A periodic task T_i is a sequence of jobs $J_{i,1}, J_{i,2}, \ldots J_{i,n}, \ldots$ with the constant differences between release times of consecutive jobs, the constant execution times, and the constant relative deadlines of all jobs.

- The phase φ_i of a task T_i is the release time r_{i,1} of the first job J_{i,1} in the task T_i; tasks are in phase if their phases are equal
- The period p_i of a task T_i is the length of the constant time interval between release times of consecutive jobs in T_i
- The execution time e_i of a task T_i is the constant execution time of all jobs in T_i
- The relative deadline D_i is the constant relative deadline of all jobs in T_i

The 4-tuple $T_i = (\varphi_i, p_i, e_i, D_i)$ refers to a periodic task T_i with phase φ_i , period p_i , execution time e_i , and relative deadline D_i

The 4-tuple $T_i = (\varphi_i, p_i, e_i, D_i)$ refers to a periodic task T_i with phase φ_i , period p_i , execution time e_i , and relative deadline D_i

For example: jobs of $T_1 = (1, 10, 3, 6)$ are

- released at times 1, 11, 21, ...,
- execute for 3 time units,
- have to be finished in 6 time units (the first by 7, the second by 17, ...)

The 4-tuple $T_i = (\varphi_i, p_i, e_i, D_i)$ refers to a periodic task T_i with phase φ_i , period p_i , execution time e_i , and relative deadline D_i

For example: jobs of $T_1 = (1, 10, 3, 6)$ are

- released at times 1, 11, 21, ...,
- execute for 3 time units,
- have to be finished in 6 time units (the first by 7, the second by 17, ...)

Default phase of T_i is $\varphi_i = 0$ and default relative deadline is $d_i = p_i$

 $T_2 = (10, 3, 6)$ satisfies $\varphi = 0$, $p_i = 10$, $e_i = 3$, $D_i = 6$, i.e. jobs of T_2 are

- released at times 0, 10, 20, ...,
- execute for 3 time units,
- have to be finished in 6 time units (the first by 6, the second by 16, ...)

The 4-tuple $T_i = (\varphi_i, p_i, e_i, D_i)$ refers to a periodic task T_i with phase φ_i , period p_i , execution time e_i , and relative deadline D_i

For example: jobs of $T_1 = (1, 10, 3, 6)$ are

- released at times 1, 11, 21, ...,
- execute for 3 time units,
- have to be finished in 6 time units (the first by 7, the second by 17, ...)

Default phase of T_i is $\varphi_i = 0$ and default relative deadline is $d_i = p_i$

 $T_2 = (10, 3, 6)$ satisfies $\varphi = 0$, $p_i = 10$, $e_i = 3$, $D_i = 6$, i.e. jobs of T_2 are

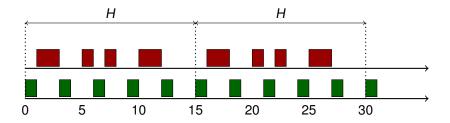

- released at times 0, 10, 20, …,
- execute for 3 time units,
- have to be finished in 6 time units (the first by 6, the second by 16, ...)

 $T_3 = (10, 3)$ satisfies $\varphi = 0$, $p_i = 10$, $e_i = 3$, $D_i = 10$, i.e. jobs of T_3 are

- released at times 0, 10, 20, …,
- execute for 3 time units,
- have to be finished in 10 time units (the first by 10, the second by 20, ...)

The *hyper-period H* of a set of periodic tasks is the least common multiple of their periods

If tasks are in phase, then H is the time instant after which the pattern of job release/execution times starts to repeat

Aperiodic and Sporadic Tasks

Many real-time systems are required to respond to external events

Aperiodic and Sporadic Tasks

- Many real-time systems are required to respond to external events
- The tasks resulting from such events are sporadic and aperiodic tasks
 - Sporadic tasks hard deadlines of jobs e.g. autopilot on/off in aircraft

The usual goal is to decide, whether a newly released job can be feasibly scheduled with the remaining jobs in the system

Aperiodic tasks – soft deadlines of jobs
 e.g. sensitivity adjustment of radar surveilance system

The usual goal is to minimize the average response time For rigorous analysis we typically assume that the inter-arrival times between aperiodic jobs are distributed according to a known distribution.

Off-line vs Online

- Off-line sched. algorithm is executed on the whole task set before activation
- Online schedule is updated at runtime every time a new task enters the system

The main division is on

- Clock-Driven
- Priority-Driven

Scheduling – Clock-Driven

- Decisions about what jobs execute when are made at specific time instants
 - these instants are chosen before the system begins execution
 - Usually regularly spaced, implemented using a periodic timer interrupt
 - Scheduler awakes after each interrupt, schedules jobs to execute for the next period, then blocks itself until the next interrupt

E.g. the helicopter example with the interrupt every 1/180 th of a second

Scheduling – Clock-Driven

- Decisions about what jobs execute when are made at specific time instants
 - these instants are chosen before the system begins execution
 - Usually regularly spaced, implemented using a periodic timer interrupt
 - Scheduler awakes after each interrupt, schedules jobs to execute for the next period, then blocks itself until the next interrupt

E.g. the helicopter example with the interrupt every 1/180 th of a second

- Typically in clock-driven systems:
 - All parameters of the real-time jobs are fixed and known
 - A schedule of the jobs is computed off-line and is stored for use at runtime; thus scheduling overhead at run-time can be minimized
 - Simple and straight-forward, not flexible

Scheduling – Priority-Driven

- Assign priorities to jobs, based on some algorithm
- Make scheduling decisions based on the priorities, when events such as releases and job completions occur
 - Priority scheduling algorithms are event-driven
 - Jobs are placed in one or more queues; at each event, the ready job with the highest priority is executed

(The assignment of jobs to priority queues, along with rules such as whether preemption is allowed, completely defines a priority-driven alg.)

Scheduling – Priority-Driven

- Assign priorities to jobs, based on some algorithm
- Make scheduling decisions based on the priorities, when events such as releases and job completions occur
 - Priority scheduling algorithms are event-driven
 - Jobs are placed in one or more queues; at each event, the ready job with the highest priority is executed

(The assignment of jobs to priority queues, along with rules such as whether preemption is allowed, completely defines a priority-driven alg.)

Priority-driven algs. make locally optimal scheduling decisions

- Locally optimal scheduling is often not globally optimal
- Priority-driven algorithms never intentionally leave idle processors

Scheduling – Priority-Driven

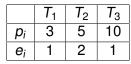

- Assign priorities to jobs, based on some algorithm
- Make scheduling decisions based on the priorities, when events such as releases and job completions occur
 - Priority scheduling algorithms are event-driven
 - Jobs are placed in one or more queues; at each event, the ready job with the highest priority is executed

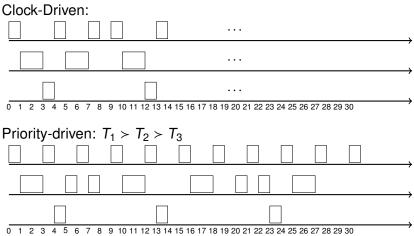

(The assignment of jobs to priority queues, along with rules such as whether preemption is allowed, completely defines a priority-driven alg.)

Priority-driven algs. make locally optimal scheduling decisions

- Locally optimal scheduling is often not globally optimal
- Priority-driven algorithms never intentionally leave idle processors
- Typically in priority-driven systems:
 - Some parameters do not have to be fixed or known
 - A schedule is computed online; usually results in larger scheduling overhead as opposed to clock-driven scheduling
 - Flexible easy to add/remove tasks or modify parameters

Clock-Driven & Priority-Driven Example

Real-Time Scheduling

Scheduling of Reactive Systems Priority-Driven Scheduling

Current Assumptions

- Single processor
- Fixed number, n, of independent periodic tasks
 - i.e. there is no dependency relation among jobs
 - Jobs can be preempted at any time and never suspend themselves
 - No aperiodic and sporadic jobs
 - No resource contentions

Current Assumptions

- Single processor
- Fixed number, *n*, of *independent periodic* tasks
 - i.e. there is no dependency relation among jobs
 - Jobs can be preempted at any time and never suspend themselves
 - No aperiodic and sporadic jobs
 - No resource contentions

Moreover, unless otherwise stated, we assume that

Scheduling decisions take place precisely at

- release of a job
- completion of a job

(and nowhere else)

Context switch overhead is negligibly small

i.e. assumed to be zero

There is an unlimited number of priority levels

Fixed-Priority vs Dynamic-Priority Algorithms

A priority-driven scheduler is on-line

i.e. it does not precompute a schedule of the tasks

- It assigns priorities to jobs after they are released and places the jobs in a ready job queue in the priority order with the highest priority jobs at the head of the queue
- At each scheduling decision time, the scheduler updates the ready job queue and then schedules and executes the job at the head of the queue

i.e. one of the jobs with the highest priority

Fixed-Priority vs Dynamic-Priority Algorithms

A priority-driven scheduler is on-line

i.e. it does not precompute a schedule of the tasks

- It assigns priorities to jobs after they are released and places the jobs in a ready job queue in the priority order with the highest priority jobs at the head of the queue
- At each scheduling decision time, the scheduler updates the ready job queue and then schedules and executes the job at the head of the queue

i.e. one of the jobs with the highest priority

Fixed-priority = all jobs in a task are assigned the same priority

Dynamic-priority = jobs in a task may be assigned different priorities

Note: In our case, a priority assigned to a job does not change. There are *job-level dynamic priority* algorithms that vary priorities of individual jobs – we won't consider such algorithms.

Fixed-priority Algorithms – Rate Monotonic

Best known fixed-priority algorithm is *rate monotonic (RM)* scheduling that assigns priorities to tasks based on their periods

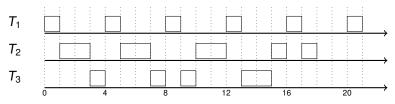

- The shorter the period, the higher the priority
- The rate is the inverse of the period, so jobs with higher rate have higher priority

RM is very widely studied and used

Example 12

 $T_1 = (4, 1), T_2 = (5, 2), T_3 = (20, 5)$ with rates 1/4, 1/5, 1/20, respectively

The priorities: $T_1 > T_2 > T_3$

Fixed-priority Algorithms – Deadline Monotonic

The *deadline monotonic (DM)* algorithm assigns priorities to tasks based on their *relative deadlines*

the shorter the deadline, the higher the priority

The *deadline monotonic (DM)* algorithm assigns priorities to tasks based on their *relative deadlines*

the shorter the deadline, the higher the priority

Observation: When relative deadline of every task matches its period, then RM and DM give the same results

Proposition 1

When the relative deadlines are arbitrary DM can sometimes produce a feasible schedule in cases where RM cannot.

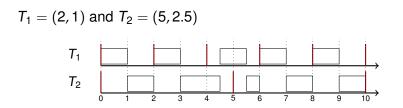

Proof.

Consider e.g. $T_1 = (3, 1, 1)$ and $T_2 = (2, 1)$.

Earliest Deadline First (EDF) assigns priorities to jobs based on their *current* absolute deadlines

At the time of a scheduling decision, the job queue is ordered by the earliest deadline the earlier the deadline, the larger the priority

We focus on EDF in this course!

Note that the processor is 100% "utilized", not surprising :-)

Least Slack Time (LST): The job queue is ordered by least slack time.

The *slack time* of a job J_i at time t is equal to $d_i - t - x$ where x is the remaining computation time of J_i at time t

There is also a strict LST which reassigns priorities to jobs whenever their slacks change relative to each other – difficult to implement This algorithm does not satisfy our assumptions!

Summary of Priority-Driven Algorithms

We consider: **Dynamic-priority:**

EDF = at the time of a scheduling decision, the job queue is ordered by the earliest deadline

Fixed-priority:

- RM = assigns priorities to tasks based on their periods
- DM = assigns priorities to tasks based on their relative deadlines

(In all cases, ties are broken arbitrarily.)

Summary of Priority-Driven Algorithms

We consider: **Dynamic-priority:**

EDF = at the time of a scheduling decision, the job queue is ordered by the earliest deadline

Fixed-priority:

- RM = assigns priorities to tasks based on their periods
- DM = assigns priorities to tasks based on their relative deadlines

(In all cases, ties are broken arbitrarily.)

We consider the following questions:

- Are the algorithms optimal?
- How to efficiently (or even online) test for schedulability?

Summary of Priority-Driven Algorithms

We consider: **Dynamic-priority:**

EDF = at the time of a scheduling decision, the job queue is ordered by the earliest deadline

Fixed-priority:

- RM = assigns priorities to tasks based on their periods
- DM = assigns priorities to tasks based on their relative deadlines

(In all cases, ties are broken arbitrarily.)

We consider the following questions:

- Are the algorithms optimal?
- How to efficiently (or even online) test for schedulability?

To measure abilities of scheduling algorithms and to get fast online tests of schedulability we use a notion of **utilization**

Utilization

Utilization u_i of a periodic task T_i with period p_i and execution time e_i is defined by u_i := e_i/p_i u_i is the fraction of time a periodic task with period p_i and execution time

ei keeps a processor busy

Utilization

- Utilization u_i of a periodic task T_i with period p_i and execution time e_i is defined by u_i := e_i/p_i u_i is the fraction of time a periodic task with period p_i and execution time e_i keeps a processor busy
- ► Total utilization U^T of a set of tasks T = {T₁,..., T_n} is defined as the sum of utilizations of all tasks of T, i.e. by

$$U^{\mathcal{T}} := \sum_{i=1}^{n} u_i$$

Utilization

- Utilization u_i of a periodic task T_i with period p_i and execution time e_i is defined by u_i := e_i/p_i u_i is the fraction of time a periodic task with period p_i and execution time e_i keeps a processor busy
- ► Total utilization U^T of a set of tasks T = {T₁,..., T_n} is defined as the sum of utilizations of all tasks of T, i.e. by

$$U^{\mathcal{T}} := \sum_{i=1}^{n} u_i$$

- U is a schedulable utilization of an algorithm ALG if all sets of tasks *T* satisfying U^T ≤ U are schedulable by ALG. Maximum schedulable utilization U_{ALG} of an algorithm ALG
 - is the supremum of schedulable utilizations of ALG.
 - If $U^{\mathcal{T}} < U_{ALG}$, then \mathcal{T} is schedulable by ALG.
 - If U > U_{ALG}, then there is T with U^T ≤ U that is not schedulable by ALG.

•
$$T_1 = (2, 1)$$
 then $u_1 = \frac{1}{2}$

•
$$T_1 = (2, 1)$$
 then $u_1 = \frac{1}{2}$

•
$$T_1 = (11, 5, 2, 4)$$
 then $u_1 = \frac{2}{5}$

(i.e., the phase and deadline do not play any role)

•
$$T_1 = (2, 1)$$
 then $u_1 = \frac{1}{2}$

►
$$T_1 = (11, 5, 2, 4)$$
 then $u_1 = \frac{2}{5}$
(i.e., the phase and deadline do not play any role)

• $\mathcal{T} = \{T_1, T_2, T_3\}$ where $T_1 = (2, 1), T_2 = (6, 1), T_3 = (8, 3)$ then

$$U^{\mathcal{T}} = \frac{1}{2} + \frac{1}{6} + \frac{3}{8} = \frac{25}{24}$$

Real-Time Scheduling

Priority-Driven Scheduling

Dynamic-Priority

Theorem 13

Let $\mathcal{T} = \{T_1, \ldots, T_n\}$ be a set of independent, preemptable periodic tasks with $D_i \ge p_i$ for $i = 1, \ldots, n$. The following statements are equivalent:

1. \mathcal{T} can be feasibly scheduled on one processor 2. $\mathcal{U}^{\mathcal{T}} \leq 1$

3. \mathcal{T} is schedulable using EDF

(i.e., in particular, $U_{EDF} = 1$)

Proof.

- **1.** \Rightarrow **2.** We prove that $U^{\mathcal{T}} > 1$ implies that \mathcal{T} is not schedulable
- **2.** \Rightarrow **3.** We prove that if EDF fails to feasibly schedule, then $U^{T} > 1$
- 3.⇒1. Trivial

Assume that $U^{\mathcal{T}} = \sum_{i=1}^{N} \frac{e_i}{p_i} > 1$.

Assume that $U^{\mathcal{T}} = \sum_{i=1}^{N} \frac{e_i}{p_i} > 1$.

Consider a time instant $t > \max_i \varphi_i$ (i.e. a time when all tasks are already "running")

Assume that
$$U^{\mathcal{T}} = \sum_{i=1}^{N} \frac{e_i}{\rho_i} > 1$$
.

Consider a time instant $t > \max_i \varphi_i$ (i.e. a time when all tasks are already "running")

Observe that the number of jobs of T_i that are released in the time interval [0, t) is $\left\lceil \frac{t-\varphi_i}{p_i} \right\rceil$. Thus a single processor needs $\sum_{i=1}^{n} \left\lceil \frac{t-\varphi_i}{p_i} \right\rceil \cdot e_i$ time units to finish all jobs *released before t*.

Assume that
$$U^{\mathcal{T}} = \sum_{i=1}^{N} \frac{e_i}{p_i} > 1$$
.

Consider a time instant $t > \max_i \varphi_i$ (i.e. a time when all tasks are already "running")

Observe that the number of jobs of T_i that are released in the time interval [0, t) is $\left\lceil \frac{t-\varphi_i}{p_i} \right\rceil$. Thus a single processor needs $\sum_{i=1}^{n} \left\lceil \frac{t-\varphi_i}{p_i} \right\rceil \cdot e_i$ time units to finish all jobs *released before t*.

However, the the total time to finish all jobs released before t is

$$\sum_{i=1}^{n} \left[\frac{t-\varphi_i}{p_i} \right] \cdot \boldsymbol{e}_i \ge \sum_{i=1}^{n} (t-\varphi_i) \cdot \frac{\boldsymbol{e}_i}{p_i} = \sum_{i=1}^{n} t \boldsymbol{u}_i - \varphi_i \boldsymbol{u}_i = \sum_{i=1}^{n} t \boldsymbol{u}_i - \sum_{i=1}^{n} \varphi_i \boldsymbol{u}_i = t \cdot \boldsymbol{U}^{\mathcal{T}} - \sum_{i=1}^{n} \varphi_i \boldsymbol{u}_i$$

Here $\sum_{i=1}^{n} \varphi_i u_i$ does not depend on *t*.

Assume that
$$U^{\mathcal{T}} = \sum_{i=1}^{N} \frac{e_i}{p_i} > 1$$
.

Consider a time instant $t > \max_i \varphi_i$ (i.e. a time when all tasks are already "running")

Observe that the number of jobs of T_i that are released in the time interval [0, t) is $\left\lceil \frac{t-\varphi_i}{p_i} \right\rceil$. Thus a single processor needs $\sum_{i=1}^{n} \left\lceil \frac{t-\varphi_i}{p_i} \right\rceil \cdot e_i$ time units to finish all jobs *released before t*.

However, the the total time to finish all jobs released before t is

$$\sum_{i=1}^{n} \left[\frac{t - \varphi_{i}}{p_{i}} \right] \cdot \boldsymbol{e}_{i} \geq \sum_{i=1}^{n} (t - \varphi_{i}) \cdot \frac{\boldsymbol{e}_{i}}{p_{i}} = \sum_{i=1}^{n} t \boldsymbol{u}_{i} - \varphi_{i} \boldsymbol{u}_{i} = \sum_{i=1}^{n} t \boldsymbol{u}_{i} - \sum_{i=1}^{n} \varphi_{i} \boldsymbol{u}_{i} = t \cdot \boldsymbol{U}^{T} - \sum_{i=1}^{n} \varphi_{i} \boldsymbol{u}_{i}$$
Here $\sum_{i=1}^{n} \varphi_{i} \boldsymbol{u}_{i}$ does not depend on t .
Note that $\lim_{t \to \infty} \left(t \cdot \boldsymbol{U}^{T} - \sum_{i=1}^{n} \varphi_{i} \boldsymbol{u}_{i} \right) - t = \infty$. So there exists t such that $t \cdot \boldsymbol{U}^{T} - \sum_{i=1}^{n} \varphi_{i} \boldsymbol{u}_{i} > t + \max_{i} D_{i}$.

Assume that
$$U^{\mathcal{T}} = \sum_{i=1}^{N} \frac{e_i}{p_i} > 1$$
.

Consider a time instant $t > \max_i \varphi_i$ (i.e. a time when all tasks are already "running")

Observe that the number of jobs of T_i that are released in the time interval [0, t) is $\left\lceil \frac{t-\varphi_i}{p_i} \right\rceil$. Thus a single processor needs $\sum_{i=1}^{n} \left\lceil \frac{t-\varphi_i}{p_i} \right\rceil \cdot e_i$ time units to finish all jobs *released before t*.

However, the the total time to finish all jobs released before t is

$$\sum_{i=1}^{n} \left[\frac{t - \varphi_{i}}{p_{i}} \right] \cdot \boldsymbol{e}_{i} \geq \sum_{i=1}^{n} (t - \varphi_{i}) \cdot \frac{\boldsymbol{e}_{i}}{p_{i}} = \sum_{i=1}^{n} t \boldsymbol{u}_{i} - \varphi_{i} \boldsymbol{u}_{i} = \sum_{i=1}^{n} t \boldsymbol{u}_{i} - \sum_{i=1}^{n} \varphi_{i} \boldsymbol{u}_{i} = t \cdot \boldsymbol{U}^{\mathcal{T}} - \sum_{i=1}^{n} \varphi_{i} \boldsymbol{u}_{i}$$
Here $\sum_{i=1}^{n} \varphi_{i} \boldsymbol{u}_{i}$ does not depend on t .

Note that $\lim_{t\to\infty} (t \cdot U^{\mathcal{T}} - \sum_{i=1}^{n} \varphi_i u_i) - t = \infty$. So there exists *t* such that $t \cdot U^{\mathcal{T}} - \sum_{i=1}^{n} \varphi_i u_i > t + \max_i D_i$.

So in order to complete all jobs released before *t* we need more time than $t + \max_i D_i$. However, the latest deadline of a job released before *t* is $t + \max_i D_i$. So at least one job misses its deadline.

Let us start with a proof of a special case (see the assumptions A1 and A2 below). Then a complete proof will be presented.

We prove $\neg 3 \Rightarrow \neg 2$. assuming that $D_i = p_i$ for i = 1, ..., n. (Note that the general case immediately follows.)

Let us start with a proof of a special case (see the assumptions A1 and A2 below). Then a complete proof will be presented.

We prove $\neg 3 \Rightarrow \neg 2$. assuming that $D_i = p_i$ for i = 1, ..., n. (Note that the general case immediately follows.)

Assume that \mathcal{T} is not schedulable according to EDF. (Our goal is to show that $U^{\mathcal{T}} > 1$.)

Let us start with a proof of a special case (see the assumptions A1 and A2 below). Then a complete proof will be presented.

We prove $\neg 3 \Rightarrow \neg 2$. assuming that $D_i = p_i$ for i = 1, ..., n. (Note that the general case immediately follows.)

Assume that \mathcal{T} is not schedulable according to EDF. (Our goal is to show that $U^{\mathcal{T}} > 1$.)

This means that there must be at least one job that misses its deadline when EDF is used.

Simplifying assumptions:

- A1 Suppose that all tasks are in phase, i.e. the phase $\varphi_{\ell} = 0$ for every task T_{ℓ} .
- A2 Suppose that the first job $J_{i,1}$ of a task T_i misses its deadline.

By A1, $J_{i,1}$ is released at 0 and misses its deadline at p_i . Assume w.l.o.g. that this is the first time when a job misses its deadline. (To simplify even further, you may (privately) assume that no other job has its deadline at p_i .)

Let G be the set of all jobs released in $[0, p_i]$ with deadlines in $[0, p_i]$.

Let G be the set of all jobs released in $[0, p_i]$ with deadlines in $[0, p_i]$.

Crucial observations:

► G contains J_{i,1}

Let G be the set of all jobs released in $[0, p_i]$ with deadlines in $[0, p_i]$.

Crucial observations:

- ► G contains J_{i,1}
- Only jobs of G can be executed in [0, p_i]

Jobs that do not belong to *G* cannot be executed in $[0, p_i]$ as $J_{i,1}$ is not completed in $[0, p_i]$ and only jobs of *G* can preempt $J_{i,1}$.

Let G be the set of all jobs released in $[0, p_i]$ with deadlines in $[0, p_i]$.

Crucial observations:

- ► G contains J_{i,1}
- Only jobs of G can be executed in [0, p_i] Jobs that do not belong to G cannot be executed in [0, p_i] as J_{i,1} is not completed in [0, p_i] and only jobs of G can preempt J_{i,1}.
- The processor is never idle in [0, p_i] The processor is not idle because J_{i,1} is ready for computation

throughout $[0, p_i]$.

Let G be the set of all jobs released in $[0, p_i]$ with deadlines in $[0, p_i]$.

Crucial observations:

- ► G contains J_{i,1}
- Only jobs of G can be executed in [0, p_i] Jobs that do not belong to G cannot be executed in [0, p_i] as J_{i,1} is not completed in [0, p_i] and only jobs of G can preempt J_{i,1}.
- The processor is never idle in [0, p_i] The processor is not idle because J_{i,1} is ready for computation throughout [0, p_i].

Denote by E_G the total execution time of G, that is, the sum of execution times of all jobs in G.

Corollary of the crucial observation: $E_G > p_i$ because otherwise $J_{i,1}$ (and all jobs that could possibly preempt it) would be completed by p_i .

Let us compute E_G .

Since we assume $\varphi_{\ell} = 0$ for every T_{ℓ} , the first job of T_{ℓ} is released at 0, and thus $\left\lfloor \frac{p_i}{p_{\ell}} \right\rfloor$ jobs of T_{ℓ} belong to *G*. E.g., if $p_{\ell} = 2$ and $p_i = 5$ then three jobs of T_{ℓ} are released in [0,5] (at times 0, 2, 4) but only $2 = \left\lfloor \frac{5}{2} \right\rfloor = \left\lfloor \frac{p_i}{p_{\ell}} \right\rfloor$ of them have their deadlines in $[0, p_i]$. Since we assume $\varphi_{\ell} = 0$ for every T_{ℓ} , the first job of T_{ℓ} is released at 0, and thus $\left\lfloor \frac{p_i}{p_{\ell}} \right\rfloor$ jobs of T_{ℓ} belong to *G*. E.g., if $p_{\ell} = 2$ and $p_i = 5$ then three jobs of T_{ℓ} are released in [0,5] (at times 0, 2, 4) but only $2 = \left\lfloor \frac{5}{2} \right\rfloor = \left\lfloor \frac{p_i}{p_{\ell}} \right\rfloor$ of them have their deadlines in $[0, p_i]$.

Thus the total execution time E_G of all jobs in G is

$$E_G = \sum_{\ell=1}^n \left\lfloor \frac{p_i}{p_\ell} \right\rfloor e_\ell$$

Since we assume $\varphi_{\ell} = 0$ for every T_{ℓ} , the first job of T_{ℓ} is released at 0, and thus $\left\lfloor \frac{p_i}{p_{\ell}} \right\rfloor$ jobs of T_{ℓ} belong to *G*. E.g., if $p_{\ell} = 2$ and $p_i = 5$ then three jobs of T_{ℓ} are released in [0,5] (at times 0, 2, 4) but only $2 = \left\lfloor \frac{5}{2} \right\rfloor = \left\lfloor \frac{p_i}{p_{\ell}} \right\rfloor$ of them have their deadlines in $[0, p_i]$.

Thus the total execution time E_G of all jobs in G is

$$E_G = \sum_{\ell=1}^n \left\lfloor \frac{p_i}{p_\ell}
ight
floorer e_\ell$$

But then

$$p_i < E_G = \sum_{\ell=1}^n \left\lfloor \frac{p_i}{p_\ell} \right\rfloor e_\ell \leq \sum_{\ell=1}^n \frac{p_i}{p_\ell} e_\ell \leq p_i \sum_{\ell=1}^n u_\ell \leq p_i \cdot U^T$$

which implies that $U^{\mathcal{T}} > 1$.

We prove $\neg 3 \Rightarrow \neg 2$. assuming that $D_i = p_i$ for i = 1, ..., n (note that the general case immediately follows)

```
We prove \neg 3. \Rightarrow \neg 2. assuming that D_i = p_i for i = 1, ..., n (note that the general case immediately follows)

Denote by E_G the sum of all execution times of all jobs in G.

Now $E_G > t - t_-$ because otherwise $J_{i,k}$ would complete in $[t_-, t]$. How to compute E_G ?

Proof of 2.⇒3. – Complete (cont.)

Now $E_G > t - t_-$ because otherwise $J_{i,k}$ would complete in $[t_-, t]$. How to compute E_G ?

For a task T_{ℓ} , denote by R_{ℓ} the earliest release time of a job in T_{ℓ} in the interval $[t_{-}, t]$.

Proof of 2.⇒3. – Complete (cont.)

Now $E_G > t - t_-$ because otherwise $J_{i,k}$ would complete in $[t_-, t]$. How to compute E_G ?

For a task T_{ℓ} , denote by R_{ℓ} the earliest release time of a job in T_{ℓ} in the interval $[t_{-}, t]$.

For every T_{ℓ} , exactly $\left\lfloor \frac{t-R_{\ell}}{\rho_{\ell}} \right\rfloor$ jobs of T_{ℓ} belong to G.

Proof of 2. \Rightarrow **3.** – **Complete (cont.)**

Now $E_G > t - t_-$ because otherwise $J_{i,k}$ would complete in $[t_-, t]$. How to compute E_G ?

For a task T_{ℓ} , denote by R_{ℓ} the earliest release time of a job in T_{ℓ} in the interval $[t_{-}, t]$.

For every T_{ℓ} , exactly $\left\lfloor \frac{t-R_{\ell}}{\rho_{\ell}} \right\rfloor$ jobs of T_{ℓ} belong to G.

Thus

$$E_G = \sum_{\ell=1}^n \left\lfloor \frac{t - R_\ell}{p_\ell} \right\rfloor e_\ell$$

Proof of 2. \Rightarrow **3.** – **Complete (cont.)**

Now $E_G > t - t_-$ because otherwise $J_{i,k}$ would complete in $[t_-, t]$. How to compute E_G ?

For a task T_{ℓ} , denote by R_{ℓ} the earliest release time of a job in T_{ℓ} in the interval $[t_{-}, t]$.

For every T_{ℓ} , exactly $\left\lfloor \frac{t-R_{\ell}}{\rho_{\ell}} \right\rfloor$ jobs of T_{ℓ} belong to G.

Thus

$$E_G = \sum_{\ell=1}^n \left\lfloor \frac{t - R_\ell}{p_\ell} \right\rfloor e_\ell$$

As argued above:

$$t-t_{-} < E_{G} = \sum_{\ell=1}^{n} \left\lfloor \frac{t-R_{\ell}}{p_{\ell}} \right\rfloor e_{\ell} \le \sum_{\ell=1}^{n} \frac{t-t_{-}}{p_{\ell}} e_{\ell} \le (t-t_{-}) \sum_{\ell=1}^{n} u_{\ell} \le (t-t_{-}) U^{\mathcal{T}}$$

which implies that $U^{\mathcal{T}} > 1$.

Density and EDF

What about tasks with $D_i < p_i$?

What about tasks with $D_i < p_i$?

Density of a task T_i with period p_i , execution time e_i and relative deadline D_i is defined by

 $e_i/\min(D_i,p_i)$

Total density $\Delta^{\mathcal{T}}$ of a set of tasks \mathcal{T} is the sum of densities of tasks in \mathcal{T} Note that if $D_i < p_i$ for some *i*, then $\Delta^{\mathcal{T}} > U^{\mathcal{T}}$ What about tasks with $D_i < p_i$?

Density of a task T_i with period p_i , execution time e_i and relative deadline D_i is defined by

 $e_i / \min(D_i, p_i)$

Total density $\Delta^{\mathcal{T}}$ of a set of tasks \mathcal{T} is the sum of densities of tasks in \mathcal{T} Note that if $D_i < p_i$ for some *i*, then $\Delta^{\mathcal{T}} > U^{\mathcal{T}}$

Theorem 14

A set \mathcal{T} of independent, preemptable, periodic tasks can be feasibly scheduled on one processor if $\Delta^{\mathcal{T}} \leq 1$.

Note that this is NOT a necessary condition!

Schedulability Test For EDF

The problem: Given a set of independent, preemptable, periodic tasks $\mathcal{T} = \{T_1, \ldots, T_n\}$ where each T_i has a period p_i , execution time e_i , and relative deadline D_i , decide whether \mathcal{T} is schedulable by EDF.

Schedulability Test For EDF

The problem: Given a set of independent, preemptable, periodic tasks $\mathcal{T} = \{T_1, \ldots, T_n\}$ where each T_i has a period p_i , execution time e_i , and relative deadline D_i , decide whether \mathcal{T} is schedulable by EDF.

Solution using utilization and density:

If $p_i \leq D_i$ for each *i*, then it suffices to decide whether $U^T \leq 1$. Otherwise, decide whether $\Delta^T \leq 1$:

- If yes, then \mathcal{T} is schedulable with EDF
- If not, then \mathcal{T} does not have to be schedulable

Schedulability Test For EDF

The problem: Given a set of independent, preemptable, periodic tasks $\mathcal{T} = \{T_1, \ldots, T_n\}$ where each T_i has a period p_i , execution time e_i , and relative deadline D_i , decide whether \mathcal{T} is schedulable by EDF.

Solution using utilization and density:

If $p_i \leq D_i$ for each *i*, then it suffices to decide whether $U^T \leq 1$. Otherwise, decide whether $\Delta^T \leq 1$:

- If yes, then \mathcal{T} is schedulable with EDF
- If not, then \mathcal{T} does not have to be schedulable

Note that

- Phases of tasks do not have to be specified
- Parameters may vary: increasing periods or deadlines, or decreasing execution times does not prevent schedulability

Consider a digital robot controller

- A control-law computation
 - takes no more than 8 ms
 - the sampling rate: 100 Hz, i.e. computes every 10 ms

Consider a digital robot controller

- A control-law computation
 - takes no more than 8 ms
 - the sampling rate: 100 Hz, i.e. computes every 10 ms

Feasible? Trivially yes

- Add Built-In Self-Test (BIST)
 - maximum execution time 50 ms
 - want a minimal period that is feasible (max one second)

Consider a digital robot controller

- A control-law computation
 - takes no more than 8 ms
 - the sampling rate: 100 Hz, i.e. computes every 10 ms

Feasible? Trivially yes

- Add Built-In Self-Test (BIST)
 - maximum execution time 50 ms
 - want a minimal period that is feasible (max one second)

With 250 ms still feasible

- Add a telemetry task
 - maximum execution time 15 ms
 - want to minimize the deadline on telemetry period may be large

Consider a digital robot controller

- A control-law computation
 - takes no more than 8 ms
 - the sampling rate: 100 Hz, i.e. computes every 10 ms

Feasible? Trivially yes

- Add Built-In Self-Test (BIST)
 - maximum execution time 50 ms
 - want a minimal period that is feasible (max one second)

With 250 ms still feasible

- Add a telemetry task
 - maximum execution time 15 ms
 - want to minimize the deadline on telemetry period may be large

Reducing BIST to once a second, deadline on telemetry may be set to 100 ms

Real-Time Scheduling

Priority-Driven Scheduling

Fixed-Priority

Any fixed-priority algorithm schedules tasks of \mathcal{T} according to fixed (distinct) priorities *assigned to tasks*.

Any fixed-priority algorithm schedules tasks of \mathcal{T} according to fixed (distinct) priorities *assigned to tasks*.

We write $T_i \supseteq T_j$ whenever T_i has a higher priority than T_j .

Any fixed-priority algorithm schedules tasks of \mathcal{T} according to fixed (distinct) priorities assigned to tasks.

We write $T_i \square T_j$ whenever T_i has a higher priority than T_j .

To simplify our reasoning, assume that

all tasks are in phase, i.e. $\varphi_k = 0$ for all T_k .

We will remove this assumption at the end.

Fixed-Priority Algorithms – Reminder

Recall that Fixed-Priority Algorithms do not have to be optimal. Consider $\mathcal{T} = \{T_1, T_2\}$ where $T_1 = (4, 2)$ and $T_2 = (6, 3)$

 $U^{\mathcal{T}} = 1$ and thus \mathcal{T} is schedulable by EDF

If $T_1 \supseteq T_2$, then $J_{2,1}$ misses its deadline If $T_2 \supseteq T_1$, then $J_{1,1}$ misses its deadline

Fixed-Priority Algorithms – Reminder

Recall that Fixed-Priority Algorithms do not have to be optimal. Consider $\mathcal{T} = \{T_1, T_2\}$ where $T_1 = (4, 2)$ and $T_2 = (6, 3)$

 $U^{\mathcal{T}} = 1$ and thus \mathcal{T} is schedulable by EDF

If $T_1 \supseteq T_2$, then $J_{2,1}$ misses its deadline If $T_2 \supseteq T_1$, then $J_{1,1}$ misses its deadline

We consider the following algorithms:

- RM = assigns priorities to tasks based on their periods the priority is inversely proportional to the period p_i
- DM = assigns priorities to tasks based on their relative deadlines the priority is inversely proportional to the relative deadline D_i

(In all cases, ties are broken arbitrarily.)

Fixed-Priority Algorithms – Reminder

Recall that Fixed-Priority Algorithms do not have to be optimal. Consider $\mathcal{T} = \{T_1, T_2\}$ where $T_1 = (4, 2)$ and $T_2 = (6, 3)$

 $U^{\mathcal{T}} = 1$ and thus \mathcal{T} is schedulable by EDF

If $T_1 \supseteq T_2$, then $J_{2,1}$ misses its deadline If $T_2 \supseteq T_1$, then $J_{1,1}$ misses its deadline

We consider the following algorithms:

- RM = assigns priorities to tasks based on their periods the priority is inversely proportional to the period p_i
- DM = assigns priorities to tasks based on their relative deadlines the priority is inversely proportional to the relative deadline D_i

(In all cases, ties are broken arbitrarily.)

We consider the following questions:

- Are the algorithms optimal?
- How to efficiently (or even online) test for schedulability?

As all tasks are in phase, the first job of T_i is released together with (first) jobs of all tasks that have higher priority than T_i .

As all tasks are in phase, the first job of T_i is released together with (first) jobs of all tasks that have higher priority than T_i .

This means, that $J_{i,1}$ is the most preempted of jobs in T_i .

As all tasks are in phase, the first job of T_i is released together with (first) jobs of all tasks that have higher priority than T_i .

This means, that $J_{i,1}$ is the most preempted of jobs in T_i .

It follows, that $J_{i,1}$ has the maximum response time. Note that this relies heavily on the assumption that tasks are in phase!

As all tasks are in phase, the first job of T_i is released together with (first) jobs of all tasks that have higher priority than T_i .

This means, that $J_{i,1}$ is the most preempted of jobs in T_i .

It follows, that $J_{i,1}$ has the maximum response time. Note that this relies heavily on the assumption that tasks are in phase!

Thus in order to decide whether \mathcal{T} is schedulable, it suffices to test for schedulability of the first jobs of all tasks.

Definition 15

A set { $T_1, ..., T_n$ } is **simply periodic** if for every pair T_i , T_ℓ satisfying $p_i > p_\ell$ we have that p_i is an integer multiple of p_ℓ

Example 16

The helicopter control system from the first lecture.

Definition 15

A set { $T_1, ..., T_n$ } is **simply periodic** if for every pair T_i , T_ℓ satisfying $p_i > p_\ell$ we have that p_i is an integer multiple of p_ℓ

Example 16

The helicopter control system from the first lecture.

Theorem 17

A set \mathcal{T} of n simply periodic, independent, preemptable tasks with $D_i = p_i$ is schedulable on one processor according to RM iff $U^{\mathcal{T}} \leq 1$. i.e. on simply periodic tasks RM is as good as EDF Note: Theorem 17 is true in general, no "in phase" assumption is needed.

By Theorem 13, every schedulable set \mathcal{T} satisfies $U^{\mathcal{T}} \leq 1$.

By Theorem 13, every schedulable set \mathcal{T} satisfies $U^{\mathcal{T}} \leq 1$.

We prove that if \mathcal{T} is not schedulable *according to RM*, then $U^{\mathcal{T}} > 1$.

By Theorem 13, every schedulable set \mathcal{T} satisfies $U^{\mathcal{T}} \leq 1$.

We prove that if \mathcal{T} is not schedulable *according to RM*, then $U^{\mathcal{T}} > 1$.

Assume that a job $J_{i,1}$ of T_i misses its deadline at $D_i = p_i$. W.I.o.g., we assume that $T_1 \supseteq \cdots \supseteq T_n$ according to RM.

By Theorem 13, every schedulable set \mathcal{T} satisfies $U^{\mathcal{T}} \leq 1$.

We prove that if \mathcal{T} is not schedulable *according to RM*, then $U^{\mathcal{T}} > 1$.

Assume that a job $J_{i,1}$ of T_i misses its deadline at $D_i = p_i$. W.I.o.g., we assume that $T_1 \supseteq \cdots \supseteq T_n$ according to RM.

Let us compute the total execution time of $J_{i,1}$ and all jobs that possibly preempt it:

$$E = e_i + \sum_{\ell=1}^{i-1} \left\lceil \frac{p_i}{p_\ell} \right\rceil e_\ell = \sum_{\ell=1}^i \frac{p_i}{p_\ell} e_\ell = p_i \sum_{\ell=1}^i u_\ell \le p_i \sum_{\ell=1}^n u_\ell = p_i U^{\mathcal{T}}$$

By Theorem 13, every schedulable set \mathcal{T} satisfies $U^{\mathcal{T}} \leq 1$.

We prove that if \mathcal{T} is not schedulable *according to RM*, then $U^{\mathcal{T}} > 1$.

Assume that a job $J_{i,1}$ of T_i misses its deadline at $D_i = p_i$. W.I.o.g., we assume that $T_1 \supseteq \cdots \supseteq T_n$ according to RM.

Let us compute the total execution time of $J_{i,1}$ and all jobs that possibly preempt it:

$$E = e_i + \sum_{\ell=1}^{i-1} \left\lceil \frac{p_i}{p_\ell} \right\rceil e_\ell = \sum_{\ell=1}^i \frac{p_i}{p_\ell} e_\ell = p_i \sum_{\ell=1}^i u_\ell \le p_i \sum_{\ell=1}^n u_\ell = p_i U^{\mathcal{T}}$$

Now $E > p_i$ because otherwise $J_{i,1}$ meets its deadline.

By Theorem 13, every schedulable set \mathcal{T} satisfies $U^{\mathcal{T}} \leq 1$.

We prove that if \mathcal{T} is not schedulable *according to RM*, then $U^{\mathcal{T}} > 1$.

Assume that a job $J_{i,1}$ of T_i misses its deadline at $D_i = p_i$. W.I.o.g., we assume that $T_1 \supseteq \cdots \supseteq T_n$ according to RM.

Let us compute the total execution time of $J_{i,1}$ and all jobs that possibly preempt it:

$$E = e_i + \sum_{\ell=1}^{i-1} \left\lceil \frac{p_i}{p_\ell} \right\rceil e_\ell = \sum_{\ell=1}^i \frac{p_i}{p_\ell} e_\ell = p_i \sum_{\ell=1}^i u_\ell \le p_i \sum_{\ell=1}^n u_\ell = p_i U^T$$

Now $E > p_i$ because otherwise $J_{i,1}$ meets its deadline. Thus

$$p_i < E \leq p_i U^T$$

and we obtain $U^{T} > 1$.

Theorem 18

A set of independent, preemptable periodic tasks with $D_i \le p_i$ that are in phase (i.e., $\varphi_i = 0$ for all i = 1, ..., n) can be feasibly scheduled on one processor according to DM if it can be feasibly scheduled by some fixed-priority algorithm.

A set of independent, preemptable periodic tasks with $D_i \le p_i$ that are in phase (i.e., $\varphi_i = 0$ for all i = 1, ..., n) can be feasibly scheduled on one processor according to DM if it can be feasibly scheduled by some fixed-priority algorithm.

Proof.

Assume a fixed-priority feasible schedule with $T_1 \sqsupset \cdots \sqsupset T_n$.

A set of independent, preemptable periodic tasks with $D_i \le p_i$ that are in phase (i.e., $\varphi_i = 0$ for all i = 1, ..., n) can be feasibly scheduled on one processor according to DM if it can be feasibly scheduled by some fixed-priority algorithm.

Proof.

Assume a fixed-priority feasible schedule with $T_1 \supseteq \cdots \supseteq T_n$.

Consider the least *i* such that the relative deadline D_i of T_i is larger than the relative deadline D_{i+1} of T_{i+1} .

A set of independent, preemptable periodic tasks with $D_i \le p_i$ that are in phase (i.e., $\varphi_i = 0$ for all i = 1, ..., n) can be feasibly scheduled on one processor according to DM if it can be feasibly scheduled by some fixed-priority algorithm.

Proof.

Assume a fixed-priority feasible schedule with $T_1 \sqsupset \cdots \sqsupset T_n$.

Consider the least *i* such that the relative deadline D_i of T_i is larger than the relative deadline D_{i+1} of T_{i+1} .

Swap the priorities of T_i and T_{i+1} .

A set of independent, preemptable periodic tasks with $D_i \le p_i$ that are in phase (i.e., $\varphi_i = 0$ for all i = 1, ..., n) can be feasibly scheduled on one processor according to DM if it can be feasibly scheduled by some fixed-priority algorithm.

Proof.

Assume a fixed-priority feasible schedule with $T_1 \sqsupset \cdots \sqsupset T_n$.

Consider the least *i* such that the relative deadline D_i of T_i is larger than the relative deadline D_{i+1} of T_{i+1} .

Swap the priorities of T_i and T_{i+1} .

The resulting schedule is still feasible.

A set of independent, preemptable periodic tasks with $D_i \le p_i$ that are in phase (i.e., $\varphi_i = 0$ for all i = 1, ..., n) can be feasibly scheduled on one processor according to DM if it can be feasibly scheduled by some fixed-priority algorithm.

Proof.

Assume a fixed-priority feasible schedule with $T_1 \supseteq \cdots \supseteq T_n$.

Consider the least *i* such that the relative deadline D_i of T_i is larger than the relative deadline D_{i+1} of T_{i+1} .

Swap the priorities of T_i and T_{i+1} .

The resulting schedule is still feasible.

DM is obtained by using finitely many swaps.

Note: If the assumptions of the above theorem hold and all relative deadlines are equal to periods, then RM is optimal among all fixed-priority algorithms.

We consider two schedulability tests:

- Schedulable utilization *U_{RM}* of the RM algorithm.
- Time-demand analysis based on response times.

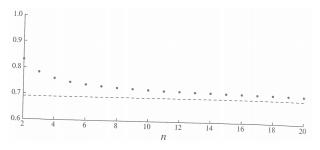

Let us fix $n \in \mathbb{N}$ and consider only independent, preemptable periodic tasks with $D_i = p_i$.

Let us fix $n \in \mathbb{N}$ and consider only independent, preemptable periodic tasks with $D_i = p_i$.

▶ If \mathcal{T} is a set of n tasks satisfying $U^{\mathcal{T}} \leq n(2^{1/n} - 1)$, then $U^{\mathcal{T}}$ is schedulable according to the RM algorithm.

Let us fix $n \in \mathbb{N}$ and consider only independent, preemptable periodic tasks with $D_i = p_i$.

- ▶ If \mathcal{T} is a set of n tasks satisfying $U^{\mathcal{T}} \leq n(2^{1/n} 1)$, then $U^{\mathcal{T}}$ is schedulable according to the RM algorithm.
- For every $U > n(2^{1/n} 1)$ there is a set \mathcal{T} of n tasks satisfying $U^{\mathcal{T}} \leq U$ that is not schedulable by RM.

Note: Theorem 19 holds in general, no "in phase" assumption is needed.

It follows that the maximum schedulable utilization U_{RM} over independent, preemptable periodic tasks satisfies

$$U_{RM} = \inf_{n} n(2^{1/n} - 1) = \lim_{n \to \infty} n(2^{1/n} - 1) = \ln 2 \approx 0.693$$

Note that $U^{\mathcal{T}} \leq n(2^{1/n} - 1)$ is a sufficient but not necessary condition for schedulability of \mathcal{T} using the RM algorithm (an example will be given later)

It follows that the maximum schedulable utilization U_{RM} over independent, preemptable periodic tasks satisfies

$$U_{RM} = \inf_{n} n(2^{1/n} - 1) = \lim_{n \to \infty} n(2^{1/n} - 1) = \ln 2 \approx 0.693$$

Note that $U^{\mathcal{T}} \leq n(2^{1/n} - 1)$ is a sufficient but not necessary condition for schedulability of \mathcal{T} using the RM algorithm (an example will be given later)

We say that a set of tasks \mathcal{T} is *RM-schedulable* if it is schedulable according to RM.

We say that \mathcal{T} is *RM-infeasible* if it is not RM-schedulable.

To simplify, we restrict to two tasks and always assume $p_1 \le p_2 \le 2p_1$. (the latter condition is w.l.o.g., proof omitted)

To simplify, we restrict to two tasks and always assume $p_1 \le p_2 \le 2p_1$. (the latter condition is w.l.o.g., proof omitted)

Outline: Given p_1 , p_2 , e_1 , denote by max_e_2 the maximum execution time so that $\mathcal{T} = \{(p_1, e_1), (p_2, max_e_2)\}$ is RM-schedulable.

To simplify, we restrict to two tasks and always assume $p_1 \le p_2 \le 2p_1$. (the latter condition is w.l.o.g., proof omitted)

Outline: Given p_1 , p_2 , e_1 , denote by max_e_2 the maximum execution time so that $\mathcal{T} = \{(p_1, e_1), (p_2, max_e_2)\}$ is RM-schedulable. We define $U_{e_1}^{p_1, p_2}$ to be $U^{\mathcal{T}}$ where $\mathcal{T} = \{(p_1, e_1), (p_2, max_e_2)\}$.

We say that \mathcal{T} fully utilizes the processor, any increase in an execution time causes RM-infeasibility.

To simplify, we restrict to two tasks and always assume $p_1 \le p_2 \le 2p_1$. (the latter condition is w.l.o.g., proof omitted)

Outline: Given p_1 , p_2 , e_1 , denote by max_e_2 the maximum execution time so that $\mathcal{T} = \{(p_1, e_1), (p_2, max_e_2)\}$ is RM-schedulable. We define $U_{e_1}^{p_1, p_2}$ to be $U^{\mathcal{T}}$ where $\mathcal{T} = \{(p_1, e_1), (p_2, max_e_2)\}$. We say that \mathcal{T} fully utilizes the processor, any increase in an execution time

causes RM-infeasibility.

Now we find the (global) minimum minU of $U_{e_1}^{p_1,p_2}$ w.r.t. all parameters p_1, p_2, e_1 .

To simplify, we restrict to two tasks and always assume $p_1 \le p_2 \le 2p_1$. (the latter condition is w.l.o.g., proof omitted)

Outline: Given p_1 , p_2 , e_1 , denote by max_e_2 the maximum execution time so that $\mathcal{T} = \{(p_1, e_1), (p_2, max_e_2)\}$ is RM-schedulable.

We define $U_{e_1}^{p_1,p_2}$ to be $U^{\mathcal{T}}$ where $\mathcal{T} = \{(p_1, e_1), (p_2, max_e_2)\}.$

We say that \mathcal{T} fully utilizes the processor, any increase in an execution time causes RM-infeasibility.

Now we find the (global) minimum minU of $U_{e_1}^{p_1,p_2}$ w.r.t. all parameters p_1, p_2, e_1 .

Note that this suffices to obtain the desired result:

► Given a set of tasks $\mathcal{T} = \{(p_1, e_1), (p_2, e_2)\}$ satisfying $U^{\mathcal{T}} \leq minU$ we get $U^{\mathcal{T}} \leq minU \leq U_{e_1}^{p_1, p_2}$, and thus the execution time e_2 cannot be larger than max_e_2 . Thus, \mathcal{T} is RM-schedulable.

To simplify, we restrict to two tasks and always assume $p_1 \le p_2 \le 2p_1$. (the latter condition is w.l.o.g., proof omitted)

Outline: Given p_1 , p_2 , e_1 , denote by max_e_2 the maximum execution time so that $\mathcal{T} = \{(p_1, e_1), (p_2, max_e_2)\}$ is RM-schedulable.

We define $U_{e_1}^{p_1,p_2}$ to be $U^{\mathcal{T}}$ where $\mathcal{T} = \{(p_1, e_1), (p_2, max_e_2)\}.$

We say that $\ensuremath{\mathcal{T}}$ fully utilizes the processor, any increase in an execution time causes RM-infeasibility.

Now we find the (global) minimum minU of $U_{e_1}^{p_1,p_2}$ w.r.t. all parameters p_1, p_2, e_1 .

Note that this suffices to obtain the desired result:

- ► Given a set of tasks $\mathcal{T} = \{(p_1, e_1), (p_2, e_2)\}$ satisfying $U^{\mathcal{T}} \leq minU$ we get $U^{\mathcal{T}} \leq minU \leq U_{e_1}^{p_1, p_2}$, and thus the execution time e_2 cannot be larger than max_e_2 . Thus, \mathcal{T} is RM-schedulable.
- Given U > minU, there must be p_1, p_2, e_1 satisfying $minU \le U_{e_1}^{p_1,p_2} < U$ where $U_{e_1}^{p_1,p_2} = U^T$ for a set of tasks $T = \{(p_1, e_1), (p_2, max_e_2)\}.$

To simplify, we restrict to two tasks and always assume $p_1 \le p_2 \le 2p_1$. (the latter condition is w.l.o.g., proof omitted)

Outline: Given p_1 , p_2 , e_1 , denote by max_e_2 the maximum execution time so that $\mathcal{T} = \{(p_1, e_1), (p_2, max_e_2)\}$ is RM-schedulable.

We define $U_{e_1}^{p_1,p_2}$ to be $U^{\mathcal{T}}$ where $\mathcal{T} = \{(p_1, e_1), (p_2, max_e_2)\}.$

We say that $\ensuremath{\mathcal{T}}$ fully utilizes the processor, any increase in an execution time causes RM-infeasibility.

Now we find the (global) minimum minU of $U_{e_1}^{p_1,p_2}$ w.r.t. all parameters p_1, p_2, e_1 .

Note that this suffices to obtain the desired result:

- ► Given a set of tasks $\mathcal{T} = \{(p_1, e_1), (p_2, e_2)\}$ satisfying $U^{\mathcal{T}} \leq minU$ we get $U^{\mathcal{T}} \leq minU \leq U_{e_1}^{p_1, p_2}$, and thus the execution time e_2 cannot be larger than max_e_2 . Thus, \mathcal{T} is RM-schedulable.
- Given U > minU, there must be p_1, p_2, e_1 satisfying $minU \le U_{e_1}^{p_1,p_2} < U$ where $U_{e_1}^{p_1,p_2} = U^T$ for a set of tasks $T = \{(p_1, e_1), (p_2, max_e_2)\}.$

However, now increasing e_1 by a sufficiently small $\varepsilon > 0$ makes the set RM-infeasible without making utilization larger than U.

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2}$$

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_2 - 2e_1}{p_2}$$

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_2 - 2e_1}{p_2} = \frac{e_1}{p_1} + \frac{p_2}{p_2} - \frac{2e_1}{p_2}$$

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_2 - 2e_1}{p_2} = \frac{e_1}{p_1} + \frac{p_2}{p_2} - \frac{2e_1}{p_2} = 1 + \frac{e_1}{p_2} \left(\frac{p_2}{p_1} - 2\right)$$

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_2 - 2e_1}{p_2} = \frac{e_1}{p_1} + \frac{p_2}{p_2} - \frac{2e_1}{p_2} = 1 + \frac{e_1}{p_2} \left(\frac{p_2}{p_1} - 2\right)$$

As $\frac{p_2}{p_1} - 2 \le 0$, the utilization $U_{e_1}^{p_1,p_2}$ is minimized by maximizing e_1 .

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

$$U_{e_{1}}^{p_{1},p_{2}} = \frac{e_{1}}{p_{1}} + \frac{max_{-}e_{2}}{p_{2}} = \frac{e_{1}}{p_{1}} + \frac{p_{2}-2e_{1}}{p_{2}} = \frac{e_{1}}{p_{1}} + \frac{p_{2}}{p_{2}} - \frac{2e_{1}}{p_{2}} = 1 + \frac{e_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}} - 2\right)$$

As $\frac{p_{2}}{p_{1}} - 2 \le 0$, the utilization $U_{e_{1}}^{p_{1},p_{2}}$ is minimized by maximizing e_{1} .
2. $e_{1} \ge p_{2} - p_{1}$:

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_2 - 2e_1}{p_2} = \frac{e_1}{p_1} + \frac{p_2}{p_2} - \frac{2e_1}{p_2} = 1 + \frac{e_1}{p_2} \left(\frac{p_2}{p_1} - 2\right)$$

As $\frac{p_2}{p_1} - 2 \le 0$, the utilization $U_{e_1}^{p_1,p_2}$ is minimized by maximizing e_1 .
2. $e_1 \ge p_2 - p_1$:
Maximum RM-feasible max_e_2 (with p_1, p_2, e_1) is $p_1 - e_1$.

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

Maximum RM-feasible max_e_2 (with p_1, p_2, e_1) is $p_2 - 2e_1$. Which gives the utilization

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_2 - 2e_1}{p_2} = \frac{e_1}{p_1} + \frac{p_2}{p_2} - \frac{2e_1}{p_2} = 1 + \frac{e_1}{p_2} \left(\frac{p_2}{p_1} - 2\right)$$

As $\frac{p_2}{p_1} - 2 \le 0$, the utilization $U_{e_1}^{p_1,p_2}$ is minimized by maximizing e_1 .
2. $e_1 \ge p_2 - p_1$:
Maximum RM-feasible max_e_2 (with p_1, p_2, e_1) is $p_1 - e_1$. Which gives the utilization

 $U_{e_1}^{p_1,p_2}$

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_2 - 2e_1}{p_2} = \frac{e_1}{p_1} + \frac{p_2}{p_2} - \frac{2e_1}{p_2} = 1 + \frac{e_1}{p_2} \left(\frac{p_2}{p_1} - 2\right)$$

As $\frac{p_2}{p_1} - 2 \le 0$, the utilization $U_{e_1}^{p_1,p_2}$ is minimized by maximizing e_1 .
2. $e_1 \ge p_2 - p_1$:
Maximum RM-feasible max_e_2 (with p_1, p_2, e_1) is $p_1 - e_1$. Which gives the utilization

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2}$$

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_2 - 2e_1}{p_2} = \frac{e_1}{p_1} + \frac{p_2}{p_2} - \frac{2e_1}{p_2} = 1 + \frac{e_1}{p_2} \left(\frac{p_2}{p_1} - 2\right)$$

As $\frac{p_2}{p_1} - 2 \le 0$, the utilization $U_{e_1}^{p_1,p_2}$ is minimized by maximizing e_1 .
2. $e_1 \ge p_2 - p_1$:
Maximum RM-feasible max_e_2 (with p_1, p_2, e_1) is $p_1 - e_1$. Which gives the utilization

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_1 - e_1}{p_2}$$

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_2 - 2e_1}{p_2} = \frac{e_1}{p_1} + \frac{p_2}{p_2} - \frac{2e_1}{p_2} = 1 + \frac{e_1}{p_2} \left(\frac{p_2}{p_1} - 2\right)$$
As $\frac{p_2}{p_1} - 2 \le 0$, the utilization $U_{e_1}^{p_1,p_2}$ is minimized by maximizing e_1 .
2. $e_1 \ge p_2 - p_1$:
Maximum RM-feasible max_e_2 (with p_1, p_2, e_1) is $p_1 - e_1$. Which gives the utilization

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_1 - e_1}{p_2} = \frac{e_1}{p_1} + \frac{p_1}{p_2} - \frac{e_1}{p_2}$$

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

Maximum RM-feasible max_e_2 (with p_1, p_2, e_1) is $p_2 - 2e_1$. Which gives the utilization

 $U_{e_{1}}^{p_{1},p_{2}} = \frac{e_{1}}{p_{1}} + \frac{max_e_{2}}{p_{2}} = \frac{e_{1}}{p_{1}} + \frac{p_{2}-2e_{1}}{p_{2}} = \frac{e_{1}}{p_{1}} + \frac{p_{2}}{p_{2}} - \frac{2e_{1}}{p_{2}} = 1 + \frac{e_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}} - 2\right)$ As $\frac{p_{2}}{p_{1}} - 2 \le 0$, the utilization $U_{e_{1}}^{p_{1},p_{2}}$ is minimized by maximizing e_{1} . **2.** $e_{1} \ge p_{2} - p_{1}$: Maximum RM-feasible max_e_{2} (with p_{1}, p_{2}, e_{1}) is $p_{1} - e_{1}$. Which gives the utilization

$$U_{e_1}^{p_1,p_2} = \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_1 - e_1}{p_2} = \frac{e_1}{p_1} + \frac{p_1}{p_2} - \frac{e_1}{p_2} = \frac{p_1}{p_2} + \frac{e_1}{p_2} \left(\frac{p_2}{p_1} - 1\right)$$

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

Maximum RM-feasible max_e_2 (with p_1, p_2, e_1) is $p_2 - 2e_1$. Which gives the utilization

$$U_{e_{1}}^{p_{1},p_{2}} = \frac{e_{1}}{p_{1}} + \frac{max_e_{2}}{p_{2}} = \frac{e_{1}}{p_{1}} + \frac{p_{2}-2e_{1}}{p_{2}} = \frac{e_{1}}{p_{1}} + \frac{p_{2}}{p_{2}} - \frac{2e_{1}}{p_{2}} = 1 + \frac{e_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}} - 2\right)$$
As $\frac{p_{2}}{p_{1}} - 2 \le 0$, the utilization $U_{e_{1}}^{p_{1},p_{2}}$ is minimized by maximizing e_{1} .
2. $e_{1} \ge p_{2} - p_{1}$:
Maximum RM-feasible max_e_{2} (with p_{1}, p_{2}, e_{1}) is $p_{1} - e_{1}$. Which gives the utilization
 $U_{e_{1}}^{p_{1},p_{2}} = \frac{e_{1}}{p_{1}} + \frac{max_e_{2}}{p_{2}} = \frac{e_{1}}{p_{1}} + \frac{p_{1} - e_{1}}{p_{2}} = \frac{e_{1}}{p_{1}} + \frac{p_{1}}{p_{2}} - \frac{e_{1}}{p_{2}} = \frac{p_{1}}{p_{2}} + \frac{e_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}} - 1\right)$

As $\frac{p_2}{p_1} - 1 \ge 0$, the utilization $U_{e_1}^{p_1,p_2}$ is minimized by minimizing e_1 .

First, minimize w.r.t. e_1 (p_1 , p_2 fixed). Two cases depending on e_1 :

1. $e_1 < p_2 - p_1$:

Maximum RM-feasible max_e_2 (with p_1, p_2, e_1) is $p_2 - 2e_1$. Which gives the utilization

 $\begin{aligned} U_{e_1}^{p_1,p_2} &= \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_2 - 2e_1}{p_2} = \frac{e_1}{p_1} + \frac{p_2}{p_2} - \frac{2e_1}{p_2} = 1 + \frac{e_1}{p_2} \left(\frac{p_2}{p_1} - 2\right) \\ \text{As } \frac{p_2}{p_1} - 2 &\leq 0, \text{ the utilization } U_{e_1}^{p_1,p_2} \text{ is minimized by maximizing } e_1. \\ \textbf{2. } e_1 &\geq p_2 - p_1 : \\ \text{Maximum RM-feasible } max_e_2 \text{ (with } p_1, p_2, e_1) \text{ is } p_1 - e_1. \text{ Which gives the utilization } \\ U_{e_1}^{p_1,p_2} &= \frac{e_1}{p_1} + \frac{max_e_2}{p_2} = \frac{e_1}{p_1} + \frac{p_1 - e_1}{p_2} = \frac{e_1}{p_1} + \frac{p_1}{p_2} - \frac{e_1}{p_2} = \frac{p_1}{p_2} + \frac{e_1}{p_2} \left(\frac{p_2}{p_1} - 1\right) \\ \text{As } \frac{p_2}{p_1} - 1 \geq 0, \text{ the utilization } U_{e_1}^{p_1,p_2} \text{ is minimized by minimizing } e_1. \end{aligned}$

In both cases, the minimum of $U_{e_1}^{p_1,p_2}$ is attained at $e_1 = p_2 - p_1$. (Both expressions defining $U_{e_1}^{p_1,p_2}$ give the same value for $e_1 = p_2 - p_1$.)

Substitute $e_1 = p_2 - p_1$ into the expression for $U_{e_1}^{p_1,p_2}$:

Substitute $e_1 = p_2 - p_1$ into the expression for $U_{e_1}^{p_1,p_2}$:

$$U_{p_2-p_1}^{p_1,p_2} = \frac{p_1}{p_2} + \frac{p_2 - p_1}{p_2} \left(\frac{p_2}{p_1} - 1\right) = \frac{p_1}{p_2} + \left(1 - \frac{p_1}{p_2}\right) \left(\frac{p_2}{p_1} - 1\right)$$
$$= \frac{p_1}{p_2} + \frac{p_1}{p_2} \left(\frac{p_2}{p_1} - 1\right) \left(\frac{p_2}{p_1} - 1\right) = \frac{p_1}{p_2} \left(1 + \left(\frac{p_2}{p_1} - 1\right)^2\right)$$

Substitute $e_1 = p_2 - p_1$ into the expression for $U_{e_1}^{p_1,p_2}$:

$$U_{p_{2}-p_{1}}^{p_{1},p_{2}} = \frac{p_{1}}{p_{2}} + \frac{p_{2}-p_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}}-1\right) = \frac{p_{1}}{p_{2}} + \left(1-\frac{p_{1}}{p_{2}}\right) \left(\frac{p_{2}}{p_{1}}-1\right)$$
$$= \frac{p_{1}}{p_{2}} + \frac{p_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}}-1\right) \left(\frac{p_{2}}{p_{1}}-1\right) = \frac{p_{1}}{p_{2}} \left(1+\left(\frac{p_{2}}{p_{1}}-1\right)^{2}\right)$$

Denoting $G = \frac{p_2}{p_1} - 1$ we obtain

 $U_{p_2-p_1}^{p_1,p_2}$

Substitute $e_1 = p_2 - p_1$ into the expression for $U_{e_1}^{p_1,p_2}$:

$$U_{p_{2}-p_{1}}^{p_{1},p_{2}} = \frac{p_{1}}{p_{2}} + \frac{p_{2}-p_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}}-1\right) = \frac{p_{1}}{p_{2}} + \left(1-\frac{p_{1}}{p_{2}}\right) \left(\frac{p_{2}}{p_{1}}-1\right)$$
$$= \frac{p_{1}}{p_{2}} + \frac{p_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}}-1\right) \left(\frac{p_{2}}{p_{1}}-1\right) = \frac{p_{1}}{p_{2}} \left(1+\left(\frac{p_{2}}{p_{1}}-1\right)^{2}\right)$$

Denoting $G = \frac{p_2}{p_1} - 1$ we obtain

$$U_{p_2-p_1}^{p_1,p_2}=rac{p_1}{p_2}(1+G^2)$$

Substitute $e_1 = p_2 - p_1$ into the expression for $U_{e_1}^{p_1,p_2}$:

$$U_{p_{2}-p_{1}}^{p_{1},p_{2}} = \frac{p_{1}}{p_{2}} + \frac{p_{2}-p_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}}-1\right) = \frac{p_{1}}{p_{2}} + \left(1-\frac{p_{1}}{p_{2}}\right) \left(\frac{p_{2}}{p_{1}}-1\right)$$
$$= \frac{p_{1}}{p_{2}} + \frac{p_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}}-1\right) \left(\frac{p_{2}}{p_{1}}-1\right) = \frac{p_{1}}{p_{2}} \left(1+\left(\frac{p_{2}}{p_{1}}-1\right)^{2}\right)$$

Denoting $G = \frac{p_2}{p_1} - 1$ we obtain

$$U_{p_2-p_1}^{p_1,p_2} = \frac{p_1}{p_2}(1+G^2) = \frac{1+G^2}{p_2/p_1}$$

Substitute $e_1 = p_2 - p_1$ into the expression for $U_{e_1}^{p_1,p_2}$:

$$U_{p_{2}-p_{1}}^{p_{1},p_{2}} = \frac{p_{1}}{p_{2}} + \frac{p_{2}-p_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}}-1\right) = \frac{p_{1}}{p_{2}} + \left(1-\frac{p_{1}}{p_{2}}\right) \left(\frac{p_{2}}{p_{1}}-1\right)$$
$$= \frac{p_{1}}{p_{2}} + \frac{p_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}}-1\right) \left(\frac{p_{2}}{p_{1}}-1\right) = \frac{p_{1}}{p_{2}} \left(1+\left(\frac{p_{2}}{p_{1}}-1\right)^{2}\right)$$

Denoting $G = \frac{p_2}{p_1} - 1$ we obtain

$$U_{p_2-p_1}^{p_1,p_2} = \frac{p_1}{p_2}(1+G^2) = \frac{1+G^2}{p_2/p_1} = \frac{1+G^2}{1+G}$$

Substitute $e_1 = p_2 - p_1$ into the expression for $U_{e_1}^{p_1,p_2}$:

$$U_{p_{2}-p_{1}}^{p_{1},p_{2}} = \frac{p_{1}}{p_{2}} + \frac{p_{2}-p_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}}-1\right) = \frac{p_{1}}{p_{2}} + \left(1-\frac{p_{1}}{p_{2}}\right) \left(\frac{p_{2}}{p_{1}}-1\right)$$
$$= \frac{p_{1}}{p_{2}} + \frac{p_{1}}{p_{2}} \left(\frac{p_{2}}{p_{1}}-1\right) \left(\frac{p_{2}}{p_{1}}-1\right) = \frac{p_{1}}{p_{2}} \left(1+\left(\frac{p_{2}}{p_{1}}-1\right)^{2}\right)$$

Denoting $G = \frac{p_2}{p_1} - 1$ we obtain

$$U_{\rho_2-\rho_1}^{p_1,\rho_2} = \frac{p_1}{p_2}(1+G^2) = \frac{1+G^2}{p_2/p_1} = \frac{1+G^2}{1+G}$$

Differentiating w.r.t. G we get

$$\frac{G^2 + 2G - 1}{(1+G)^2}$$

which is equal to zero at $G = -1 \pm \sqrt{2}$. Here only $G = -1 + \sqrt{2} > 0$ is acceptable since the other root is negative.

Thus the minimum value of $U_{e_1}^{p_1,p_2}$ is

$$\frac{1+(\sqrt{2}-1)^2}{1+(\sqrt{2}-1)} = \frac{4-2\sqrt{2}}{\sqrt{2}} = 2(\sqrt{2}-1)$$

Thus the minimum value of $U_{e_1}^{p_1,p_2}$ is

$$\frac{1 + (\sqrt{2} - 1)^2}{1 + (\sqrt{2} - 1)} = \frac{4 - 2\sqrt{2}}{\sqrt{2}} = 2(\sqrt{2} - 1)$$

It is attained at periods satisfying

$$G = \frac{p_2}{p_1} - 1 = \sqrt{2} - 1$$
 i.e. satisfying $p_2 = \sqrt{2}p_1$.

Thus the minimum value of $U_{e_1}^{p_1,p_2}$ is

$$\frac{1+(\sqrt{2}-1)^2}{1+(\sqrt{2}-1)} = \frac{4-2\sqrt{2}}{\sqrt{2}} = 2(\sqrt{2}-1)$$

It is attained at periods satisfying

$$G = \frac{p_2}{p_1} - 1 = \sqrt{2} - 1$$
 i.e. satisfying $p_2 = \sqrt{2}p_1$.

The execution time e_1 which at full utilization of the processor (due to max_e_2) gives the minimum utilization is

 $e_1 = p_2 - p_1 = (\sqrt{2} - 1)p_1$

Thus the minimum value of $U_{e_1}^{p_1,p_2}$ is

$$\frac{1+(\sqrt{2}-1)^2}{1+(\sqrt{2}-1)} = \frac{4-2\sqrt{2}}{\sqrt{2}} = 2(\sqrt{2}-1)$$

It is attained at periods satisfying

$$G = \frac{p_2}{p_1} - 1 = \sqrt{2} - 1$$
 i.e. satisfying $p_2 = \sqrt{2}p_1$.

The execution time e_1 which at full utilization of the processor (due to max_e_2) gives the minimum utilization is

 $e_1 = p_2 - p_1 = (\sqrt{2} - 1)p_1$

and the corresponding $max_{e_2} = p_1 - e_1 = p_1 - (p_2 - p_1) = 2p_1 - p_2$.

Thus the minimum value of $U_{e_1}^{p_1,p_2}$ is

$$\frac{1+(\sqrt{2}-1)^2}{1+(\sqrt{2}-1)} = \frac{4-2\sqrt{2}}{\sqrt{2}} = 2(\sqrt{2}-1)$$

It is attained at periods satisfying

$$G = \frac{p_2}{p_1} - 1 = \sqrt{2} - 1$$
 i.e. satisfying $p_2 = \sqrt{2}p_1$.

The execution time e_1 which at full utilization of the processor (due to max_e_2) gives the minimum utilization is

 $e_1 = p_2 - p_1 = (\sqrt{2} - 1)p_1$

and the corresponding $max_{e_2} = p_1 - e_1 = p_1 - (p_2 - p_1) = 2p_1 - p_2$.

Scaling to $p_1 = 1$, we obtain a completely determined example $p_1 = 1$ $p_2 = \sqrt{2} \approx 1.41$ $e_1 = \sqrt{2}-1 \approx 0.41$ $max_e_2 = 2-\sqrt{2} \approx 0.59$ that maximally utilizes the processor (no execution time can be increased) but has the minimum utilization $2(\sqrt{2}-1)$.

Proof Idea of Theorem 19

Fix periods $p_1 < \cdots < p_n$ so that (w.l.o.g.) $p_n \le 2p_1$. Then the following set of tasks has the smallest utilization among all task sets that fully utilize the processor (i.e., any increase in any execution time makes the set unschedulable).

Consider a set of *n* tasks $\mathcal{T} = \{T_1, \ldots, T_n\}$.

Recall that we consider only independent, preemptable, in phase (i.e. $\varphi_i = 0$ for all *i*) tasks without resource contentions.

Consider a set of *n* tasks $\mathcal{T} = \{T_1, \ldots, T_n\}$.

Recall that we consider only independent, preemptable, in phase (i.e. $\varphi_i = 0$ for all *i*) tasks without resource contentions.

Assume that $D_i \le p_i$ for every *i*, and consider an arbitrary fixed-priority algorithm. W.I.o.g. assume $T_1 \sqsupset \cdots \sqsupset T_n$.

Consider a set of *n* tasks $\mathcal{T} = \{T_1, \ldots, T_n\}$.

Recall that we consider only independent, preemptable, in phase (i.e. $\varphi_i = 0$ for all *i*) tasks without resource contentions.

Assume that $D_i \le p_i$ for every *i*, and consider an arbitrary fixed-priority algorithm. W.I.o.g. assume $T_1 \sqsupset \cdots \sqsupset T_n$.

Idea: For every task T_i and every time instant $t \ge 0$, compute the total execution time $w_i(t)$ (the time demand) of the first job $J_{i,1}$ and of all higher-priority jobs released up to time t.

If $w_i(t) \le t$ for some time $t \le D_i$, then $J_{i,1}$ is schedulable, and hence all jobs of T_i are schedulable.

Consider one task T_i at a time, starting with highest priority and working to lowest priority.

- Consider one task T_i at a time, starting with highest priority and working to lowest priority.
- Focus on the first job $J_{i,1}$ of T_i .

If $J_{i,1}$ makes it, all jobs of T_i will make it due to $\varphi_i = 0$.

- Consider one task T_i at a time, starting with highest priority and working to lowest priority.
- Focus on the first job $J_{i,1}$ of T_i .

If $J_{i,1}$ makes it, all jobs of T_i will make it due to $\varphi_i = 0$.

At time t for t ≥ 0, the processor time demand w_i(t) for this job and all higher-priority jobs released in [0, t) is bounded by

$$w_i(t) = e_i + \sum_{\ell=1}^{i-1} \left\lceil \frac{t}{p_\ell} \right\rceil e_\ell \qquad ext{ for } 0 < t \le p_i$$

(Note that the smallest *t* for which $w_i(t) \le t$ is the response time of $J_{i,1}$, and hence the maximum response time of jobs in T_i).

- Consider one task T_i at a time, starting with highest priority and working to lowest priority.
- Focus on the first job $J_{i,1}$ of T_i .

If $J_{i,1}$ makes it, all jobs of T_i will make it due to $\varphi_i = 0$.

At time t for t ≥ 0, the processor time demand w_i(t) for this job and all higher-priority jobs released in [0, t) is bounded by

$$w_i(t) = e_i + \sum_{\ell=1}^{i-1} \left\lceil \frac{t}{p_\ell} \right\rceil e_\ell \qquad ext{ for } 0 < t \le p_i$$

(Note that the smallest *t* for which $w_i(t) \le t$ is the response time of $J_{i,1}$, and hence the maximum response time of jobs in T_i).

▶ If $w_i(t) \le t$ for some $t \le D_i$, the job $J_{i,1}$ meets its deadline D_i .

Consider one task T_i at a time, starting with highest priority and working to lowest priority.

Focus on the first job
$$J_{i,1}$$
 of T_i .

If $J_{i,1}$ makes it, all jobs of T_i will make it due to $\varphi_i = 0$.

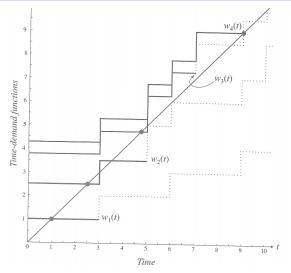

At time t for t ≥ 0, the processor time demand w_i(t) for this job and all higher-priority jobs released in [0, t) is bounded by

$$w_i(t) = e_i + \sum_{\ell=1}^{i-1} \left\lceil \frac{t}{p_\ell} \right\rceil e_\ell \qquad ext{ for } 0 < t \le p_i$$

(Note that the smallest *t* for which $w_i(t) \le t$ is the response time of $J_{i,1}$, and hence the maximum response time of jobs in T_i).

- ▶ If $w_i(t) \le t$ for some $t \le D_i$, the job $J_{i,1}$ meets its deadline D_i .
- If w_i(t) > t for all 0 < t ≤ D_i, then the first job of the task cannot complete by its deadline.

Time-Demand Analysis – Example

Example: $T_1 = (3, 1), T_2 = (5, 1.5), T_3 = (7, 1.25), T_4 = (9, 0.5)$

This set of tasks is schedulable by RM even though $U^{\{T_1,...,T_4\}} = 0.85 > 0.757 = U_{RM}(4)$

- The time-demand function $w_i(t)$ is a staircase function
 - Steps in the time-demand for a task occur at multiples of the period for higher-priority tasks

- Steps in the time-demand for a task occur at multiples of the period for higher-priority tasks
- The value of w_i(t) t linearly decreases from a step until the next step

- Steps in the time-demand for a task occur at multiples of the period for higher-priority tasks
- The value of w_i(t) t linearly decreases from a step until the next step

- Steps in the time-demand for a task occur at multiples of the period for higher-priority tasks
- The value of w_i(t) t linearly decreases from a step until the next step
- If our interest is the schedulability of a task, it suffices to check if w_i(t) ≤ t at the time instants when a higher-priority job is released and at D_i

- Steps in the time-demand for a task occur at multiples of the period for higher-priority tasks
- The value of w_i(t) t linearly decreases from a step until the next step
- If our interest is the schedulability of a task, it suffices to check if w_i(t) ≤ t at the time instants when a higher-priority job is released and at D_i
- Our schedulability test becomes:
 - Compute w_i(t)
 - Check whether $w_i(t) \le t$ for some t equal either to D_i , or to
 - $j \cdot p_k$ where k = 1, 2, ..., i and $j = 1, 2, ..., \lfloor D_i / p_k \rfloor$

Time-demand analysis schedulability test is more complex than the schedulable utilization test but more general:

- Time-demand analysis schedulability test is more complex than the schedulable utilization test but more general:
 - ► Works for any fixed-priority scheduling algorithm, provided the tasks have short response time (D_i ≤ p_i) Can be extended to tasks with arbitrary deadlines

- Time-demand analysis schedulability test is more complex than the schedulable utilization test but more general:
 - ► Works for any fixed-priority scheduling algorithm, provided the tasks have short response time (D_i ≤ p_i) Can be extended to tasks with arbitrary deadlines
- Still more efficient than exhaustive simulation.

- Time-demand analysis schedulability test is more complex than the schedulable utilization test but more general:
 - ► Works for *any* fixed-priority scheduling algorithm, provided the tasks have short response time (D_i ≤ p_i) Can be extended to tasks with arbitrary deadlines
- Still more efficient than exhaustive simulation.
- Assuming that the tasks are in phase the time demand analysis is complete.

- Time-demand analysis schedulability test is more complex than the schedulable utilization test but more general:
 - ► Works for any fixed-priority scheduling algorithm, provided the tasks have short response time (D_i ≤ p_i) Can be extended to tasks with arbitrary deadlines
- Still more efficient than exhaustive simulation.
- Assuming that the tasks are in phase the time demand analysis is complete.

We have considered the time demand analysis for tasks in phase. In particular, we used the fact that the first job has the maximum response time.

- Time-demand analysis schedulability test is more complex than the schedulable utilization test but more general:
 - ► Works for any fixed-priority scheduling algorithm, provided the tasks have short response time (D_i ≤ p_i) Can be extended to tasks with arbitrary deadlines
- Still more efficient than exhaustive simulation.
- Assuming that the tasks are in phase the time demand analysis is complete.

We have considered the time demand analysis for tasks in phase. In particular, we used the fact that the first job has the maximum response time.

This is not true if the jobs are not in phase, we need to identify the so called *critical instant*, the time instant in which the system is most loaded, and has its worst response time.

Critical Instant – Formally

A **critical instant** t_{crit} of a task T_i is a time instant in which a job $J_{i,k}$ in T_i is released so that $J_{i,k}$ either does not meet its deadline, or has the maximum response time of all jobs in T_i .

Theorem 20

Assume $D_i \le p_i$ for every *i* and use a fixed-priority algorithm. A critical instant of a task T_i occurs when one of its jobs $J_{i,k}$ is released at the same time with a job from every higher-priority task.

Critical Instant – Formally

A **critical instant** t_{crit} of a task T_i is a time instant in which a job $J_{i,k}$ in T_i is released so that $J_{i,k}$ either does not meet its deadline, or has the maximum response time of all jobs in T_i .

Theorem 20

Assume $D_i \le p_i$ for every *i* and use a fixed-priority algorithm. A critical instant of a task T_i occurs when one of its jobs $J_{i,k}$ is released at the same time with a job from every higher-priority task.

Note that the situation described in the theorem does not have to occur if tasks are not in phase!

Critical Instant – Formally

A **critical instant** t_{crit} of a task T_i is a time instant in which a job $J_{i,k}$ in T_i is released so that $J_{i,k}$ either does not meet its deadline, or has the maximum response time of all jobs in T_i .

Theorem 20

Assume $D_i \le p_i$ for every *i* and use a fixed-priority algorithm. A critical instant of a task T_i occurs when one of its jobs $J_{i,k}$ is released at the same time with a job from every higher-priority task.

Note that the situation described in the theorem does not have to occur if tasks are not in phase!

To get such a critical instant, we set phases of all tasks to zero, which gives a new set of tasks $\mathcal{T}' = \{T'_1, \dots, T'_n\}$. Denote jobs of T'_i by $J'_{i,k}$.

Critical Instant – Formally

A **critical instant** t_{crit} of a task T_i is a time instant in which a job $J_{i,k}$ in T_i is released so that $J_{i,k}$ either does not meet its deadline, or has the maximum response time of all jobs in T_i .

Theorem 20

Assume $D_i \le p_i$ for every *i* and use a fixed-priority algorithm. A critical instant of a task T_i occurs when one of its jobs $J_{i,k}$ is released at the same time with a job from every higher-priority task.

Note that the situation described in the theorem does not have to occur if tasks are not in phase!

To get such a critical instant, we set phases of all tasks to zero, which gives a new set of tasks $\mathcal{T}' = \{T'_1, \dots, T'_n\}$. Denote jobs of T'_i by $J'_{i,k}$.

Corollary 21

Assume $D_i \le p_i$ for every i and use a fixed-priority algorithm. Consider a critical instant t_{crit} of a task T_i .

- If the job J_{i,k} released at t_{crit} misses its deadline, then J'_{i,1} misses its deadline.
- Otherwise, the response time of J_{i,k} is at most as large as the response time of J'_{i,1}.

Set phases of all tasks to zero, which gives a new set of tasks $T' = \{T'_1, \ldots, T'_n\}.$

Set phases of all tasks to zero, which gives a new set of tasks $T' = \{T'_1, \ldots, T'_n\}.$

Decide schedulability of \mathcal{T}' , e.g., using the timed-demand analysis.

Set phases of all tasks to zero, which gives a new set of tasks $T' = \{T'_1, \dots, T'_n\}.$

Decide schedulability of \mathcal{T}' , e.g., using the timed-demand analysis.

• If \mathcal{T}' if schedulable, then also \mathcal{T} is schedulable.

Set phases of all tasks to zero, which gives a new set of tasks $T' = \{T'_1, \dots, T'_n\}.$

Decide schedulability of \mathcal{T}' , e.g., using the timed-demand analysis.

- If \mathcal{T}' if schedulable, then also \mathcal{T} is schedulable.
- If T' is not schedulable, then T does not have to be schedulable. But may be schedulable, which make the time-demand analysis incomplete in general for tasks not in phase.

- ► EDF
 - pros:
 - optimal
 - very simple and complete test for schedulability

► EDF

- pros:
 - optimal
 - very simple and complete test for schedulability
- cons:
 - difficult to predict which job misses its deadline
 - strictly following EDF in case of overloads assigns higher priority to jobs that missed their deadlines
 - larger scheduling overhead

► EDF

- pros:
 - optimal
 - very simple and complete test for schedulability
- cons:
 - difficult to predict which job misses its deadline
 - strictly following EDF in case of overloads assigns higher priority to jobs that missed their deadlines
 - larger scheduling overhead
- DM (RM)
 - pros:
 - easier to predict which job misses its deadline (in particular, tasks are not blocked by lower priority tasks)
 - easy implementation with little scheduling overhead
 - (optimal in some cases often occurring in practice)

► EDF

- pros:
 - optimal
 - very simple and complete test for schedulability
- cons:
 - difficult to predict which job misses its deadline

 - easy implementation with little scheduling overhead
 - (optimal in some cases often occurring in practice)
 - cons:
 - not optimal
 - incomplete and more involved tests for schedulability

Real-Time Scheduling

Priority-Driven Scheduling

Aperiodic Tasks

Current Assumptions

We slightly abuse notation and talk about *preriodic/aperiodic/sporadic jobs* meaning jobs of periodic/aperiodic/sporadic tasks.

- Single processor
- Fixed number, n, of independent periodic tasks

Jobs can be preempted at any time and never suspend themselves, no resource contentions

Current Assumptions

We slightly abuse notation and talk about *preriodic/aperiodic/sporadic jobs* meaning jobs of periodic/aperiodic/sporadic tasks.

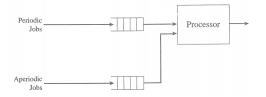

- Single processor
- Fixed number, n, of independent periodic tasks

Jobs can be preempted at any time and never suspend themselves, no resource contentions

Aperiodic jobs exist

They are independent of each other and of the periodic tasks. Can be preempted at any time.

- No sporadic jobs (for now)
- Jobs are scheduled using a priority driven algorithm

Scheduling Aperiodic Jobs

Consider:

- A set $\mathcal{T} = \{T_1, \ldots, T_n\}$ of periodic tasks
- An aperiodic task A

Scheduling Aperiodic Jobs

Consider:

- A set $\mathcal{T} = \{T_1, \ldots, T_n\}$ of periodic tasks
- An aperiodic task A

Recall that:

- A schedule is feasible if all jobs with hard real-time constraints complete before their deadlines
 - \Rightarrow This includes all periodic jobs

Scheduling Aperiodic Jobs

Consider:

- A set $\mathcal{T} = \{T_1, \ldots, T_n\}$ of periodic tasks
- An aperiodic task A

Recall that:

- A schedule is feasible if all jobs with hard real-time constraints complete before their deadlines
 - \Rightarrow This includes all periodic jobs
- A scheduling algorithm is optimal if it always produces a feasible schedule whenever such a schedule exists, and if a cost function is given, minimizes the cost

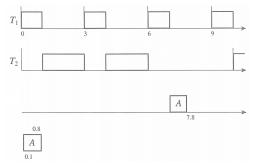

Aperiodic jobs are scheduled and executed only at times when there are no periodic jobs ready for execution

- Aperiodic jobs are scheduled and executed only at times when there are no periodic jobs ready for execution
- Advantages
 - Clearly produces feasible schedules
 - Extremely simple to implement

- Aperiodic jobs are scheduled and executed only at times when there are no periodic jobs ready for execution
- Advantages
 - Clearly produces feasible schedules
 - Extremely simple to implement
- Disadvantages
 - Not optimal since the execution of aperiodic jobs may be unnecessarily delayed

- Aperiodic jobs are scheduled and executed only at times when there are no periodic jobs ready for execution
- Advantages
 - Clearly produces feasible schedules
 - Extremely simple to implement
- Disadvantages
 - Not optimal since the execution of aperiodic jobs may be unnecessarily delayed

Example: $T_1 = (3, 1), T_2 = (10, 4)$

► We may use a *polling server*

- We may use a polling server
 - A periodic task (p_s, e_s) scheduled according to the periodic algorithm, generally as the highest priority task

- We may use a polling server
 - A periodic task (p_s, e_s) scheduled according to the periodic algorithm, generally as the highest priority task
 - When executed, it examines the aperiodic job queue

- We may use a polling server
 - A periodic task (p_s, e_s) scheduled according to the periodic algorithm, generally as the highest priority task
 - When executed, it examines the aperiodic job queue
 - If an aperiodic job is in the queue, it is executed for up to es time units

- We may use a polling server
 - A periodic task (p_s, e_s) scheduled according to the periodic algorithm, generally as the highest priority task
 - When executed, it examines the aperiodic job queue
 - If an aperiodic job is in the queue, it is executed for up to es time units
 - If the aperiodic queue is empty, the polling server self-suspends, giving up its execution slot

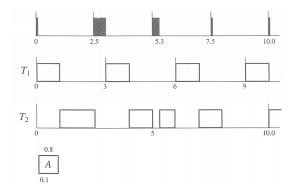

We may use a polling server

- A periodic task (p_s, e_s) scheduled according to the periodic algorithm, generally as the highest priority task
- When executed, it examines the aperiodic job queue
 - If an aperiodic job is in the queue, it is executed for up to es time units
 - If the aperiodic queue is empty, the polling server self-suspends, giving up its execution slot
 - The server does not wake-up once it has self-suspended, aperiodic jobs which become active during the period are not considered for execution until the next period begins

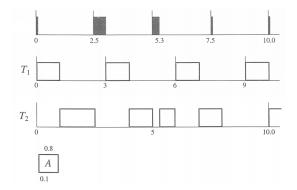

We may use a polling server

- A periodic task (p_s, e_s) scheduled according to the periodic algorithm, generally as the highest priority task
- When executed, it examines the aperiodic job queue
 - If an aperiodic job is in the queue, it is executed for up to es time units
 - If the aperiodic queue is empty, the polling server self-suspends, giving up its execution slot
 - The server does not wake-up once it has self-suspended, aperiodic jobs which become active during the period are not considered for execution until the next period begins
- Simple to prove correctness, performance less than ideal executes aperiodic jobs in particular timeslots

Example: $T_1 = (3, 1), T_2 = (10, 4), poller = (2.5, 0.5)$

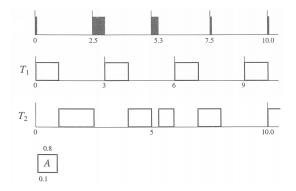

Example: $T_1 = (3, 1), T_2 = (10, 4), poller = (2.5, 0.5)$

Can we do better?

Example: $T_1 = (3, 1), T_2 = (10, 4), poller = (2.5, 0.5)$

Can we do better?

Yes, polling server is a special case of *periodic-server* for aperiodic jobs.

periodic server = a task that behaves much like a periodic task, but is created for the purpose of executing aperiodic jobs

Periodic Severs – Terminology

periodic server = a task that behaves much like a periodic task, but is created for the purpose of executing aperiodic jobs

• A periodic server, $T_S = (p_S, e_S)$

Periodic Severs – Terminology

periodic server = a task that behaves much like a periodic task, but is created for the purpose of executing aperiodic jobs

• A periodic server, $T_S = (p_S, e_S)$

p_S is a period of the server

Periodic Severs – Terminology

periodic server = a task that behaves much like a periodic task, but is created for the purpose of executing aperiodic jobs

- A periodic server, $T_S = (p_S, e_S)$
 - *p_S* is a period of the server
 - e_S is the (maximal) budget of the server

periodic server = a task that behaves much like a periodic task, but is created for the purpose of executing aperiodic jobs

- A periodic server, $T_S = (p_S, e_S)$
 - *p_S* is a period of the server
 - e_S is the (maximal) budget of the server
- The budget can be consumed and replenished; the budget is exhausted when it reaches 0

(Periodic servers differ in how they consume and replenish the budget)

- A periodic server, $T_S = (p_S, e_S)$
 - *p_S* is a period of the server
 - e_S is the (maximal) budget of the server
- The budget can be consumed and replenished; the budget is exhausted when it reaches 0

(Periodic servers differ in how they consume and replenish the budget)

A periodic server is

- A periodic server, $T_S = (p_S, e_S)$
 - *p_S* is a period of the server
 - e_S is the (maximal) budget of the server
- The budget can be consumed and replenished; the budget is exhausted when it reaches 0

(Periodic servers differ in how they consume and replenish the budget)

- A periodic server is
 - backlogged whenever the aperiodic job queue is non-empty

- A periodic server, $T_S = (p_S, e_S)$
 - *p_S* is a period of the server
 - e_S is the (maximal) budget of the server
- The budget can be consumed and replenished; the budget is exhausted when it reaches 0

(Periodic servers differ in how they consume and replenish the budget)

- A periodic server is
 - backlogged whenever the aperiodic job queue is non-empty
 - idle if the queue is empty

- A periodic server, $T_S = (p_S, e_S)$
 - *p_S* is a period of the server
 - e_S is the (maximal) budget of the server
- The budget can be consumed and replenished; the budget is exhausted when it reaches 0

(Periodic servers differ in how they consume and replenish the budget)

A periodic server is

- backlogged whenever the aperiodic job queue is non-empty
- idle if the queue is empty
- eligible if it is backlogged and the budget is not exhausted

- A periodic server, $T_S = (p_S, e_S)$
 - *p_S* is a period of the server
 - e_S is the (maximal) budget of the server
- The budget can be consumed and replenished; the budget is exhausted when it reaches 0

(Periodic servers differ in how they consume and replenish the budget)

A periodic server is

- backlogged whenever the aperiodic job queue is non-empty
- idle if the queue is empty
- eligible if it is backlogged and the budget is not exhausted
- When a periodic server is eligible, it is scheduled as any other periodic task with parameters (p_S, e_S)

Each periodic server is thus specified by

- consumption rules: How the budget is consumed
- replenishment rules: When and how the budget is replenished

Each periodic server is thus specified by

- consumption rules: How the budget is consumed
- replenishment rules: When and how the budget is replenished

Polling server

- consumption rules:
 - Whenever the server executes, the budget is consumed at the rate one per unit time.
 - Whenever the server becomes idle, the budget gets immediately exhausted
- replenishment rule: At each time instant k · p_S replenish the budget to e_S

Deferrable sever

Consumption rules:

Deferrable sever

- Consumption rules:
 - The budget is consumed at the rate of one per unit time whenever the server executes

Deferrable sever

- Consumption rules:
 - The budget is consumed at the rate of one per unit time whenever the server executes
 - Unused budget is retained throughout the period, to be used whenever there are aperiodic jobs to execute (i.e. instead of discarding the budget if no aperiodic job to execute at start of period, keep in the hope a job arrives)

Deferrable sever

- Consumption rules:
 - The budget is consumed at the rate of one per unit time whenever the server executes
 - Unused budget is retained throughout the period, to be used whenever there are aperiodic jobs to execute (i.e. instead of discarding the budget if no aperiodic job to execute at start of period, keep in the hope a job arrives)
- Replenishment rule:

Deferrable sever

- Consumption rules:
 - The budget is consumed at the rate of one per unit time whenever the server executes
 - Unused budget is retained throughout the period, to be used whenever there are aperiodic jobs to execute (i.e. instead of discarding the budget if no aperiodic job to execute at start of period, keep in the hope a job arrives)
- Replenishment rule:
 - The budget is set to e_S at multiples of the period

• i.e. time instants $k \cdot p_S$ for k = 0, 1, 2, ...

(Note that the server is not able tu cumulate the budget over periods)

Deferrable sever

- Consumption rules:
 - The budget is consumed at the rate of one per unit time whenever the server executes
 - Unused budget is retained throughout the period, to be used whenever there are aperiodic jobs to execute (i.e. instead of discarding the budget if no aperiodic job to execute at start of period, keep in the hope a job arrives)
- Replenishment rule:
 - The budget is set to e_S at multiples of the period
 - i.e. time instants $k \cdot p_S$ for k = 0, 1, 2, ...

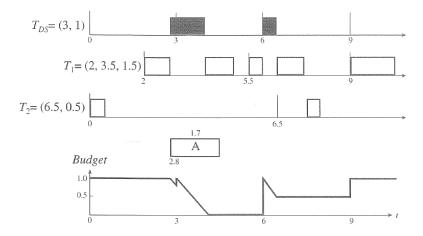

(Note that the server is not able tu cumulate the budget over periods)

We consider both

- Fixed-priority scheduling
- Dynamic-priority scheduling (EDF)

Deferrable Server – RM

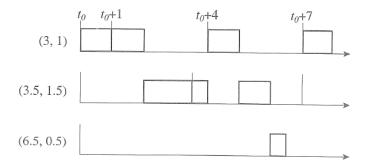

Here the tasks are scheduled using RM.

Is it possible to increase the budget of the server to 1.5?

Deferrable Server – RM

Consider $T_1 = (3.5, 1.5)$, $T_2 = (6.5, 0.5)$ and $T_{DS} = (3, 1)$ A **critical instant** for $T_1 = (3.5, 1.5)$ looks as follows:

i.e. increasing the budget above 1 may cause T_1 to miss its deadline

Assume a fixed-priority scheduling algorithm. Assume that $D_i \leq p_i$ and that the deferrable server (p_S, e_S) has the highest priority among all tasks.

Assume a fixed-priority scheduling algorithm. Assume that $D_i \leq p_i$ and that the deferrable server (p_S, e_S) has the highest priority among all tasks. Then a critical instant of every periodic task T_i occurs at a time t_0 when all of the following are true:

One of its jobs J_{i,c} is released at t₀

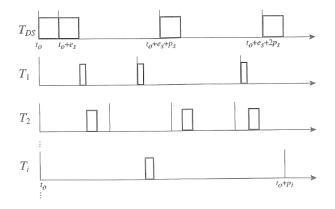

- One of its jobs J_{i,c} is released at t₀
- A job in every higher-priority periodic task is released at t₀

- One of its jobs J_{i,c} is released at t₀
- A job in every higher-priority periodic task is released at t₀
- The budget of the server is e_S at t₀, one or more aperiodic jobs are released at t₀, and they keep the server backlogged hereafter

- One of its jobs J_{i,c} is released at t₀
- A job in every higher-priority periodic task is released at t₀
- The budget of the server is e_S at t₀, one or more aperiodic jobs are released at t₀, and they keep the server backlogged hereafter
- The next replenishment time of the server is $t_0 + e_S$

Deferrable Server – Critical Instant

Assume $T_{DS} \supseteq T_1 \supseteq T_2 \supseteq \cdots \supseteq T_n$ (i.e. T_1 has the highest pririty and T_n lowest)

Assume that the deferrable server has the highest priority

The definition of critical instant is identical to that for the periodic tasks without the deferrable server + the worst-case requirements for the server

Assume that the deferrable server has the highest priority

- The definition of critical instant is identical to that for the periodic tasks without the deferrable server + the worst-case requirements for the server
- Thus the expression for the time-demand function becomes

$$w_i(t) = e_i + \sum_{k=1}^{i-1} \left[\frac{t}{p_k} \right] e_k + e_s + \left[\frac{t - e_s}{p_s} \right] e_s \qquad \text{for } 0 < t \le p_i$$

Assume that the deferrable server has the highest priority

- The definition of critical instant is identical to that for the periodic tasks without the deferrable server + the worst-case requirements for the server
- Thus the expression for the time-demand function becomes

$$w_i(t) = e_i + \sum_{k=1}^{i-1} \left[\frac{t}{p_k} \right] e_k + e_s + \left[\frac{t - e_s}{p_s} \right] e_s \qquad \text{for } 0 < t \le p_i$$

To determine whether the task *T_i* is schedulable, we simply check whether *w_i*(*t*) ≤ *t* for some *t* ≤ *D_i*. Note that this is a *sufficient condition*, not necessary.

Assume that the deferrable server has the highest priority

- The definition of critical instant is identical to that for the periodic tasks without the deferrable server + the worst-case requirements for the server
- Thus the expression for the time-demand function becomes

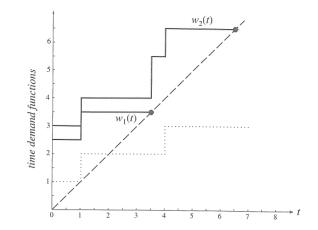

$$w_i(t) = e_i + \sum_{k=1}^{i-1} \left[\frac{t}{p_k} \right] e_k + e_s + \left[\frac{t - e_s}{p_s} \right] e_s \qquad \text{for } 0 < t \le p_i$$

To determine whether the task *T_i* is schedulable, we simply check whether *w_i*(*t*) ≤ *t* for some *t* ≤ *D_i*

Note that this is a *sufficient condition*, not necessary.

- Check whether $w_i(t) \le t$ for some t equal either
 - to D_i , or
 - ▶ to $j \cdot p_k$ where k = 1, 2, ..., i and $j = 1, 2, ..., \lfloor D_i / p_k \rfloor$, or
 - to $e_S, e_S + p_S, e_S + 2p_S, \dots, e_S + \lfloor (D_i e_i)/p_S \rfloor p_S$

$$T_{DS} = (3, 1.0), T_1 = (3.5, 1.5), T_2 = (6.5, 0.5)$$

Deferrable Server – Schedulable Utilization

No maximum schedulable utilization is known in general

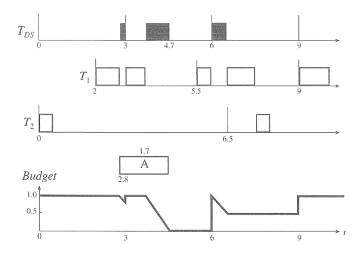

- No maximum schedulable utilization is known in general
- A special case:
 - A set *T* of *n* independent, preemptable periodic tasks whose periods satisfy $p_S < p_1 < \cdots < p_n < 2p_S$ and $p_n > p_S + e_S$ and whose relative deadlines are equal to their respective periods, can be scheduled according to RM with a deferrable server provided that

$$U^{T} \leq U_{RM/DS}(n) := (n-1) \left[\left(\frac{u_{S}+2}{u_{S}+1} \right)^{\frac{1}{n-1}} - 1 \right]$$

where $u_S = e_S/p_S$

Deferrable Server – EDF

Here the tasks are scheduled using EDF. $T_{DS} = (3, 1), T_1 = (2, 3.5, 1.5), T_2 = (6.5, 0.5)$

Theorem 23

A set of n independent, preemptable, periodic tasks satisfying $p_i \le D_i$ for all $1 \le i \le n$ is schedulable with a deferrable server with period p_S , execution budget e_S and utilization $u_S = e_S/p_S$ according to the EDF algorithm if:

$$\sum_{k=1}^n u_k + u_S \left(1 + \frac{p_S - e_S}{\min_i D_i} \right) \le 1$$

Sporadic Server – Motivation

- Problem with polling server: T_{PS} = (p_S, e_S) executes aperiodic jobs at the multiples of p_S
- Problem with deferrable server: T_{DS} = (p_S, e_S) may delay lower priority jobs longer than a periodic task with the same parameters (p_S, e_S)

Therefore special version of time-demand analysis and utilization bounds are needed.

Sporadic Server – Motivation

- Problem with polling server: T_{PS} = (p_S, e_S) executes aperiodic jobs at the multiples of p_S
- Problem with deferrable server: T_{DS} = (p_S, e_S) may delay lower priority jobs longer than a periodic task with the same parameters (p_S, e_S)

Therefore special version of time-demand analysis and utilization

bounds are needed.

- Sporadic server $T_{SS} = (e_S, p_S)$
 - may execute jobs "in the middle" of its period
 - never delays periodic tasks longer than the periodic task (p_S, e_S)

Thus can be tested for schedulability as an ordinary periodic task.

Sporadic Server – Motivation

- Problem with polling server: T_{PS} = (p_S, e_S) executes aperiodic jobs at the multiples of p_S
- Problem with deferrable server: T_{DS} = (p_S, e_S) may delay lower priority jobs longer than a periodic task with the same parameters (p_S, e_S)

Therefore special version of time-demand analysis and utilization

bounds are needed.

- Sporadic server $T_{SS} = (e_S, p_S)$
 - may execute jobs "in the middle" of its period
 - never delays periodic tasks longer than the periodic task (p_S, e_S)

Thus can be tested for schedulability as an ordinary periodic task.

Originally proposed by Sprunt, Sha, Lehoczky in 1989

original version contains a bug which allows longer delay of lower priority jobs

Part of POSIX standard

also incorrect as observed and (probably) corrected by Stanovich in 2010

Very Simple Sporadic Server

For simplicity, we consider only fixed priority scheduling, i.e., assume $T_1 \supseteq T_2 \supseteq \cdots \supseteq T_n$ and consider a sporadic server $T_{SS} = (p_S, e_S)$ with the *highest priority*

Notation:

- *t_r* = the *latest* replenishment time
- t_f = first instant after t_r at which server begins to execute
- n_r = a variable representing the *next* replenishment

Very Simple Sporadic Server

For simplicity, we consider only fixed priority scheduling, i.e., assume $T_1 \supseteq T_2 \supseteq \cdots \supseteq T_n$ and consider a sporadic server $T_{SS} = (p_S, e_S)$ with the *highest priority*

Notation:

- *t_r* = the *latest* replenishment time
- t_f = first instant after t_r at which server begins to execute
- n_r = a variable representing the *next* replenishment
- Consumption rule: The budget is consumed (at the rate of one per unit time) whenever the current time *t* satisfies *t* ≥ *t_f*

For simplicity, we consider only fixed priority scheduling, i.e., assume $T_1 \supseteq T_2 \supseteq \cdots \supseteq T_n$ and consider a sporadic server $T_{SS} = (p_S, e_S)$ with the *highest priority*

- Replenishment rules: At the beginning, $t_r = n_r = 0$
 - Whenever the current time is equal to n_r, the budget is set to e_S and t_r is set to the current time
 - At the beginning of an idle interval of *T*, the budget is set to e_S and n_r is set to the end of this interval

New notation:

- ► *t_r* = the *latest* replenishment time
- *t_f* = first instant after *t_r* at which server begins to execute and *at* least one task of *T* is not idle
- $n_r = a$ variable representing the *next* replenishment
- Consumption rule: The budget is consumed (at the rate of one per unit time) whenever the current time *t* satisfies *t* ≥ *t*_f and at least one task of *T* is not idle

• Replenishment rules: At the beginning, $t_r = n_r = 0$

- Whenever the current time is equal to n_r, the budget is set to e_S and t_r is set to the current time
- At the beginning of an idle interval of *T*, the budget is set to e_S and n_r is set to the end of this interval
- At the first instant t_f after t_r at which the server starts executing and \mathcal{T} is not idle, n_r is set to $t_f + p_S$

This combines the very simple sporadic server with background scheduling.

Correctness (informally):

Assuming that \mathcal{T} never idles, the sporadic server resembles a periodic task with the highest priority whose jobs are released at times t_f and execution times are at most e_S

Correctness (informally):

Assuming that \mathcal{T} never idles, the sporadic server resembles a periodic task with the highest priority whose jobs are released at times t_f and execution times are at most e_S

Whenever \mathcal{T} idles, the sporadic server executes in the background, i.e., does not block any periodic task, hence does not consume the budget

Correctness (informally):

Assuming that \mathcal{T} never idles, the sporadic server resembles a periodic task with the highest priority whose jobs are released at times t_f and execution times are at most e_S

Whenever \mathcal{T} idles, the sporadic server executes in the background, i.e., does not block any periodic task, hence does not consume the budget

Whenever an idle interval of \mathcal{T} ends, we may treat this situation as a restart of the system with possibly different phases of tasks (so that it is safe to have the budget equal to e_S)

Correctness (informally):

Assuming that \mathcal{T} never idles, the sporadic server resembles a periodic task with the highest priority whose jobs are released at times t_f and execution times are at most e_S

Whenever \mathcal{T} idles, the sporadic server executes in the background, i.e., does not block any periodic task, hence does not consume the budget

Whenever an idle interval of \mathcal{T} ends, we may treat this situation as a restart of the system with possibly different phases of tasks (so that it is safe to have the budget equal to e_S)

Note that in both versions of the sporadic server, e_S units of execution time are available for aper. jobs every p_S units of time This means that if the server is always backlogged, then it executes for e_S time units every p_S units of time

Real-Time Scheduling

Priority-Driven Scheduling

Sporadic Tasks

Current Assumptions

Single processor

- Fixed number, *n*, of *independent periodic* tasks, T_1, \ldots, T_n where $T_i = (\varphi_i, p_i, e_i, D_i)$
 - Jobs can be preempted at any time and never suspend themselves

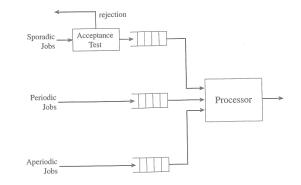

No resource contentions

- Sporadic tasks
 - Independent of the periodic tasks
 - Jobs can be preempted at any time
- Aperiodic tasks

For simplicity scheduled in the background - i.e. we may ignore them

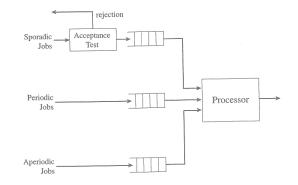

Jobs are scheduled using a priority driven algorithm

Our situation

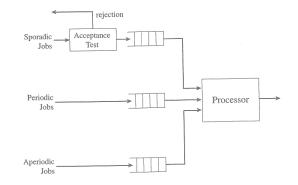

Based on the execution time and deadline of each newly arrived sporadic job, decide whether to accept or reject the job

Our situation

- Based on the execution time and deadline of each newly arrived sporadic job, decide whether to accept or reject the job
- Accepting the job implies that the job will complete within its deadline, without causing any periodic job or previously accepted sporadic job to miss its deadline

Our situation

- Based on the execution time and deadline of each newly arrived sporadic job, decide whether to accept or reject the job
- Accepting the job implies that the job will complete within its deadline, without causing any periodic job or previously accepted sporadic job to miss its deadline
- Do not accept a sporadic job if cannot guarantee it will meet its deadline

Scheduling Sporadic Jobs – Correctness and Optimality

A correct schedule is one where all periodic tasks, and all sporadic jobs that have been accepted, meet their deadlines

Scheduling Sporadic Jobs – Correctness and Optimality

- A correct schedule is one where all periodic tasks, and all sporadic jobs that have been accepted, meet their deadlines
- A scheduling algorithm supporting sporadic jobs is a correct algorithm if it only produces correct schedules for the system

Scheduling Sporadic Jobs – Correctness and Optimality

- A correct schedule is one where all periodic tasks, and all sporadic jobs that have been accepted, meet their deadlines
- A scheduling algorithm supporting sporadic jobs is a correct algorithm if it only produces correct schedules for the system
- A sporadic job scheduling algorithm is *optimal* if the following holds:

It accepts a new sporadic job and schedules that job to complete by its deadline **iff** the new job can be correctly scheduled to complete in time

- Assume that all jobs in the system are scheduled by EDF
- if more sporadic jobs are released at the same time their acceptance test is done in the EDF order

- Assume that all jobs in the system are scheduled by EDF
- if more sporadic jobs are released at the same time their acceptance test is done in the EDF order
- Definitions:
 - Sporadic jobs are denoted by S(r, d, e) where r is the release time, d the (absolute) deadline, and e is the maximum execution time

- Assume that all jobs in the system are scheduled by EDF
- if more sporadic jobs are released at the same time their acceptance test is done in the EDF order
- Definitions:
 - Sporadic jobs are denoted by S(r, d, e) where r is the release time, d the (absolute) deadline, and e is the maximum execution time
 - The **density** of S(r, d, e) is defined by e/(d r)

- Assume that all jobs in the system are scheduled by EDF
- if more sporadic jobs are released at the same time their acceptance test is done in the EDF order
- Definitions:
 - Sporadic jobs are denoted by S(r, d, e) where r is the release time, d the (absolute) deadline, and e is the maximum execution time
 - The **density** of S(r, d, e) is defined by e/(d r)
 - The total density of a set of sporadic jobs is the sum of densities of these jobs

- Assume that all jobs in the system are scheduled by EDF
- if more sporadic jobs are released at the same time their acceptance test is done in the EDF order
- Definitions:
 - Sporadic jobs are denoted by S(r, d, e) where r is the release time, d the (absolute) deadline, and e is the maximum execution time
 - The **density** of S(r, d, e) is defined by e/(d r)
 - The total density of a set of sporadic jobs is the sum of densities of these jobs
 - ▶ The sporadic job S(r, d, e) is active at time t iff $t \in (r, d]$

- Assume that all jobs in the system are scheduled by EDF
- if more sporadic jobs are released at the same time their acceptance test is done in the EDF order
- Definitions:
 - Sporadic jobs are denoted by S(r, d, e) where r is the release time, d the (absolute) deadline, and e is the maximum execution time
 - The **density** of S(r, d, e) is defined by e/(d r)
 - The total density of a set of sporadic jobs is the sum of densities of these jobs
 - ► The sporadic job S(r, d, e) is active at time t iff $t \in (r, d]$

Note that each job of a periodic task (φ , p, e, D) can be seen as a sporadic job; to simplify, we **assume that always** $D \le p$.

This in turn means that there is always at most one job of a given task active at a given time instant.

For every job of this task released at *r* with abs. deadline *d*, we obtain the density e/(d - r) = e/D

Schedulability of Sporadic Jobs with EDF

Theorem 24

A set of independent preemptable sporadic jobs is schedulable according to EDF if at every time instant t the total density of all jobs active at time t is at most one.

Schedulability of Sporadic Jobs with EDF

Theorem 24

A set of independent preemptable sporadic jobs is schedulable according to EDF if at every time instant t the total density of all jobs active at time t is at most one.

Proof.

By contradiction, suppose that a job misses its deadline at t, no deadlines missed before t

Schedulability of Sporadic Jobs with EDF

Theorem 24

A set of independent preemptable sporadic jobs is schedulable according to EDF if at every time instant t the total density of all jobs active at time t is at most one.

Proof.

By contradiction, suppose that a job misses its deadline at t, no deadlines missed before t

Let t_1 be the supremum of time instants before t when either the system idles, or a job with a deadline after t executes

A set of independent preemptable sporadic jobs is schedulable according to EDF if at every time instant t the total density of all jobs active at time t is at most one.

Proof.

By contradiction, suppose that a job misses its deadline at t, no deadlines missed before t

Let t_1 be the supremum of time instants before t when either the system idles, or a job with a deadline after t executes

Suppose that jobs J_1, \ldots, J_k execute in $[t_1, t]$ and that they are ordered w.r.t. increasing deadline (J_k misses its deadline at t)

A set of independent preemptable sporadic jobs is schedulable according to EDF if at every time instant t the total density of all jobs active at time t is at most one.

Proof.

By contradiction, suppose that a job misses its deadline at t, no deadlines missed before t

Let t_1 be the supremum of time instants before t when either the system idles, or a job with a deadline after t executes

Suppose that jobs J_1, \ldots, J_k execute in $[t_1, t]$ and that they are ordered w.r.t. increasing deadline (J_k misses its deadline at t)

Let *L* be the number of releases and completions in $[t_1, t]$, denote by t_i the *i*-th time instant when *i*-th such event occurs (the first one occurs at t_1 and we denote by t_{L+1} the time instant *t*)

A set of independent preemptable sporadic jobs is schedulable according to EDF if at every time instant t the total density of all jobs active at time t is at most one.

Proof.

By contradiction, suppose that a job misses its deadline at t, no deadlines missed before t

Let t_1 be the supremum of time instants before t when either the system idles, or a job with a deadline after t executes

Suppose that jobs J_1, \ldots, J_k execute in $[t_1, t]$ and that they are ordered w.r.t. increasing deadline (J_k misses its deadline at t)

Let *L* be the number of releases and completions in $[t_1, t]$, denote by t_i the *i*-th time instant when *i*-th such event occurs (the first one occurs at t_1 and we denote by t_{L+1} the time instant t)

Denote by X_i the set of all jobs that are active during the interval $(t_i, t_{i+1}]$ and let Δ_i be their total density

A set of independent preemptable sporadic jobs is schedulable according to EDF if at every time instant t the total density of all jobs active at time t is at most one.

Proof.

By contradiction, suppose that a job misses its deadline at t, no deadlines missed before t

Let t_1 be the supremum of time instants before t when either the system idles, or a job with a deadline after t executes

Suppose that jobs J_1, \ldots, J_k execute in $[t_1, t]$ and that they are ordered w.r.t. increasing deadline (J_k misses its deadline at t)

Let *L* be the number of releases and completions in $[t_1, t]$, denote by t_i the *i*-th time instant when *i*-th such event occurs (the first one occurs at t_1 and we denote by t_{L+1} the time instant t)

Denote by X_i the set of all jobs that are active during the interval $(t_i, t_{i+1}]$ and let Δ_i be their total density

The rest on whiteboard

Note that the above theorem includes both the periodic as well as sporadic jobs

This test is sufficient but not necessary

Note that the above theorem includes both the periodic as well as sporadic jobs

This test is sufficient but not necessary

Example 25

Three sporadic jobs: $S_1(0, 2, 1)$, $S_2(0.5, 2.5, 1)$, $S_3(1, 3, 1)$

Total density at time 1.5 is 1.5

Yet, the jobs are schedulable by EDF

Let Δ be the total density of *periodic tasks*.

Let Δ be the total density of *periodic tasks*. Assume that a new sporadic job S(t, d, e) is released at time *t*.

At time t there are n active sporadic jobs in the system

- At time t there are n active sporadic jobs in the system
- The EDF scheduler maintains a list of the jobs, in non-decreasing order of their deadlines

- At time t there are n active sporadic jobs in the system
- The EDF scheduler maintains a list of the jobs, in non-decreasing order of their deadlines
 - The deadlines partition the time from t to ∞ into n + 1 discrete intervals l₁, l₂, ..., l_{n+1}

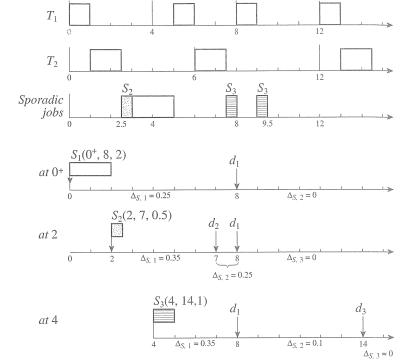

- At time t there are n active sporadic jobs in the system
- The EDF scheduler maintains a list of the jobs, in non-decreasing order of their deadlines
 - The deadlines partition the time from t to ∞ into n + 1 discrete intervals l₁, l₂,..., l_{n+1}
 - I₁ begins at t and ends at the earliest sporadic job deadline
 - For each 1 ≤ k ≤ n, each I_{k+1} begins when the interval I_k ends, and ends at the next deadline in the list (or ∞ for I_{n+1})

- At time t there are n active sporadic jobs in the system
- The EDF scheduler maintains a list of the jobs, in non-decreasing order of their deadlines
 - The deadlines partition the time from t to ∞ into n + 1 discrete intervals l₁, l₂,..., l_{n+1}

 - For each 1 ≤ k ≤ n, each I_{k+1} begins when the interval I_k ends, and ends at the next deadline in the list (or ∞ for I_{n+1})
 - The scheduler maintains the total density Δ_{S,k} of sporadic jobs active in each interval *I_k*

- At time t there are n active sporadic jobs in the system
- The EDF scheduler maintains a list of the jobs, in non-decreasing order of their deadlines
 - The deadlines partition the time from t to ∞ into n + 1 discrete intervals l₁, l₂,..., l_{n+1}
 - I₁ begins at t and ends at the earliest sporadic job deadline
 - For each 1 ≤ k ≤ n, each I_{k+1} begins when the interval I_k ends, and ends at the next deadline in the list (or ∞ for I_{n+1})
 - The scheduler maintains the total density Δ_{S,k} of sporadic jobs active in each interval *I_k*
- ► Let *I_ℓ* be the interval containing the deadline *d* of the new sporadic job *S*(*t*, *d*, *e*)

- At time t there are n active sporadic jobs in the system
- The EDF scheduler maintains a list of the jobs, in non-decreasing order of their deadlines
 - The deadlines partition the time from t to ∞ into n + 1 discrete intervals l₁, l₂,..., l_{n+1}
 - I_1 begins at t and ends at the earliest sporadic job deadline
 - For each 1 ≤ k ≤ n, each I_{k+1} begins when the interval I_k ends, and ends at the next deadline in the list (or ∞ for I_{n+1})
 - The scheduler maintains the total density Δ_{S,k} of sporadic jobs active in each interval *I_k*
- ► Let *I_ℓ* be the interval containing the deadline *d* of the new sporadic job *S*(*t*, *d*, *e*)
 - The scheduler accepts the job if e/(d − t) + Δ_{S,k} ≤ 1 − Δ for all k = 1, 2, ..., ℓ

- At time t there are n active sporadic jobs in the system
- The EDF scheduler maintains a list of the jobs, in non-decreasing order of their deadlines
 - The deadlines partition the time from t to ∞ into n + 1 discrete intervals l₁, l₂,..., l_{n+1}
 - I_1 begins at t and ends at the earliest sporadic job deadline
 - For each 1 ≤ k ≤ n, each I_{k+1} begins when the interval I_k ends, and ends at the next deadline in the list (or ∞ for I_{n+1})
 - The scheduler maintains the total density Δ_{S,k} of sporadic jobs active in each interval *I_k*
- ► Let *I_ℓ* be the interval containing the deadline *d* of the new sporadic job *S*(*t*, *d*, *e*)
 - The scheduler accepts the job if e/(d − t) + Δ_{S,k} ≤ 1 − Δ for all k = 1, 2, ..., ℓ
 - i.e. accept if the new sporadic job can be added, without increasing density of any intervals past 1

This acceptance test is not optimal: a sporadic job may be rejected even though it could be scheduled.

This acceptance test is not optimal: a sporadic job may be rejected even though it could be scheduled.

- The test is based on the density and hence is sufficient but not necessary.
- It is possible to derive a much more complex expression for schedulability which takes into account slack time, and is optimal. Unclear if the optimality is worth the complexity.

One way to schedule sporadic jobs in a fixed-priority system is to use a sporadic server to execute them

- One way to schedule sporadic jobs in a fixed-priority system is to use a sporadic server to execute them
- Because the server (p_S, e_S) has e_S units of processor time every p_S units of time, the scheduler can compute the least amount of time available to every sporadic job in the system

- One way to schedule sporadic jobs in a fixed-priority system is to use a sporadic server to execute them
- Because the server (p_S, e_S) has e_S units of processor time every p_S units of time, the scheduler can compute the least amount of time available to every sporadic job in the system
 - Assume that sporadic jobs are ordered among themselves according to EDF

- One way to schedule sporadic jobs in a fixed-priority system is to use a sporadic server to execute them
- Because the server (p_S, e_S) has e_S units of processor time every p_S units of time, the scheduler can compute the least amount of time available to every sporadic job in the system
 - Assume that sporadic jobs are ordered among themselves according to EDF
 - When first sporadic job S₁(t, d_{S,1}, e_{S,1}) arrives, there is at least

 $\lfloor (d_{S,1}-t)/p_S \rfloor e_S$

units of processor time available to the server before the deadline of the job

- One way to schedule sporadic jobs in a fixed-priority system is to use a sporadic server to execute them
- Because the server (p_S, e_S) has e_S units of processor time every p_S units of time, the scheduler can compute the least amount of time available to every sporadic job in the system
 - Assume that sporadic jobs are ordered among themselves according to EDF
 - When first sporadic job S₁(t, d_{S,1}, e_{S,1}) arrives, there is at least

 $\lfloor (d_{S,1}-t)/p_S \rfloor e_S$

units of processor time available to the server before the deadline of the job

Therefore it accepts S₁ if the slack of the job

$$\sigma_{S,1}(t) = \lfloor (d_{S,1} - t)/p_S \rfloor e_S - e_{S,1} \ge 0$$

► To decide if a new job S_i(t, d_{S,i}, e_{S,i}) is acceptable when there are *n* sporadic jobs in the system, the scheduler first computes the slack σ_{S,i}(t) of S_i:

$$\sigma_{S,i}(t) = \lfloor (d_{S,i}-t)/p_S \rfloor e_S - e_{S,i} - \sum_{d_{S,k} < d_{S,i}} (e_{S,k} - \xi_{S,k})$$

where $\xi_{S,k}$ is the execution time of the completed part of the existing job S_k

Note that the sum is taken over sporadic jobs with earlier deadline as S_i since sporadic jobs are ordered according to EDF

► To decide if a new job S_i(t, d_{S,i}, e_{S,i}) is acceptable when there are *n* sporadic jobs in the system, the scheduler first computes the slack σ_{S,i}(t) of S_i:

$$\sigma_{S,i}(t) = \lfloor (d_{S,i}-t)/p_S \rfloor e_S - e_{S,i} - \sum_{d_{S,k} < d_{S,i}} (e_{S,k} - \xi_{S,k})$$

where $\xi_{S,k}$ is the execution time of the completed part of the existing job S_k

Note that the sum is taken over sporadic jobs with earlier deadline as S_i since sporadic jobs are ordered according to EDF

• The job cannot be accepted if $\sigma_{S,i}(t) < 0$

► To decide if a new job S_i(t, d_{S,i}, e_{S,i}) is acceptable when there are *n* sporadic jobs in the system, the scheduler first computes the slack σ_{S,i}(t) of S_i:

$$\sigma_{S,i}(t) = \lfloor (d_{S,i} - t)/p_S \rfloor e_S - e_{S,i} - \sum_{d_{S,k} < d_{S,i}} (e_{S,k} - \xi_{S,k})$$

where $\xi_{S,k}$ is the execution time of the completed part of the existing job S_k

Note that the sum is taken over sporadic jobs with earlier deadline as S_i since sporadic jobs are ordered according to EDF

- The job cannot be accepted if $\sigma_{S,i}(t) < 0$
- If σ_{S,i}(t) ≥ 0, the scheduler checks if any existing sporadic job S_k with deadline equal to, or after d_{S,i} may be adversely affected by the acceptance of S_i, i.e. check if σ_{S,k}(t) ≥ e_{S,i}

Real-Time Scheduling

Resource Access Control

[Some parts of this lecture are based on a real-time systems course of Colin Perkins

http://csperkins.org/teaching/rtes/index.html]

- Mars Pathfinder = a US spacecraft that landed on Mars in July 4th, 1997.
- Consisted of a lander and a lightweight wheeled robotic Mars rover called Sojourner

The error:

- Few days in to the mission, not long after Pathfinder started gathering meteorological data, it began experiencing total system resets, each resulting in losses of data.
- Apparently a software problem caused these resets.

Single processor

Individual jobs

(that possibly belong to periodic/aperiodic/sporadic tasks)

- Jobs can be preempted at any time and never suspend themselves
- Jobs are scheduled using a priority-driven algorithm i.e., jobs are assigned priorities, scheduler executes jobs according to these priorities
- *n* resources R_1, \ldots, R_n of distinct types
 - used in non-preemptable and mutually exclusive manner; serially reusable

Motivation & Notation

Resources may represent:

- Hardware devices such as sensors and actuators
- Disk or memory capacity, buffer space
- Software resources: locks, queues, mutexes etc.

Motivation & Notation

Resources may represent:

- Hardware devices such as sensors and actuators
- Disk or memory capacity, buffer space
- Software resources: locks, queues, mutexes etc.

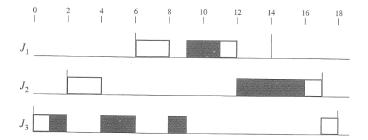

Assume a lock-based concurrency control mechanism

- A job wanting to use a resource R_k executes L(R_k) to lock the resource R_k
- When the job is finished with the resource R_k, unlocks this resource by executing U(R_k)
- If lock request fails, the requesting job is **blocked** and has to wait, when the requested resource becomes available, it is unblocked

In particular, a job holding a lock cannot be preempted by a higher priority job needing that lock

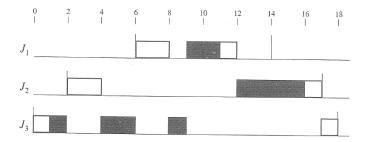

The segment of a job that begins at a lock and ends at a matching unlock is a *critical section* (CS)

CS must be properly nested if a job needs multiple resources

 J_1, J_2, J_3 scheduled according to EDF.

- At 0, J₃ is ready and executes
- At 1, J₃ executes L(R) and is granted R
- J_2 is released at 2, preempts J_3 and begins to execute
- At 4, J₂ executes L(R), becomes blocked, J₃ executes
- At 6, J₁ becomes ready, preempts J₃ and begins to execute
- At 8, J_1 executes L(R), becomes blocked, and J_3 executes

- At 9, J_3 executes U(R) and both J_1 and J_2 are unblocked. J_1 has higher priority than J_2 and executes
- ► At 11, J₁ executes U(R) and continues executing
- At 12, J₁ completes, J₂ has higher priority than J₃ and has the resource R, thus executes
- At 16, J₂ executes U(R) and continues executing
- ► At 17, *J*₂ completes, *J*₃ executes until completion at 18

The system:

- Pathfinder used the well-known real-time embedded systems kernel VxWorks by Wind River.
- VxWorks uses preemptive priority-based scheduling, in this case a deadline monotonic algorithm.
- Pathfinder contained an "information bus" (a shared memory) used for communication, synchronized by locks.

Definition 26

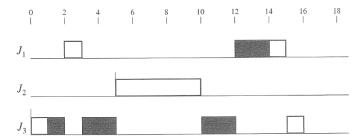

Unbounded priority inversion occurs when

- a high priority job
- is blocked by a low priority job
- which is subsequently preempted by a medium priority job

Then effectively the medium priority job executes with higher priority than the high priority job even though they do not contend for resources

There may be arbitrarily many medium priority jobs that preempt the low priority job \Rightarrow unbounded priority inversion

Unbounded priority inversion:

High priority job (J_1) can be blocked by low priority job (J_3) for unknown amount of time depending on middle priority jobs (J_2)

Definition 27 (suitable for resource access control)

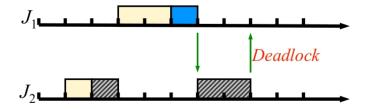

A deadlock occurs when there is a set of jobs \mathcal{D} such that each job of \mathcal{D} is waiting for a resource previously allocated by another job of \mathcal{D} .

Deadlocks can be

- detected: regularly check for deadlock, e.g., search for cycles in a resource allocation graph regularly
- avoided: postpone unsafe requests for resources even though they are available (banker's algorithm, priority-ceiling protocol)
- prevented: many methods invalidating sufficient conditions for deadlock (e.g., impose locking order on resources)

See your operating systems course for more information

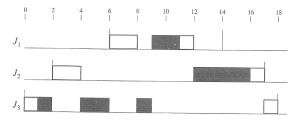

Deadlock can result from piecemeal acquisition of resources: classic example of two jobs J_1 and J_2 both needing both resources R and R'

- J_2 locks R' and J_1 locks R
- J_1 tries to get R' and is blocked
- J_2 tries to get R and is blocked

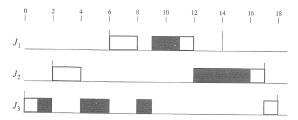

Timing Anomalies due to Resources

Previous example, the critical section of J_3 has length 4

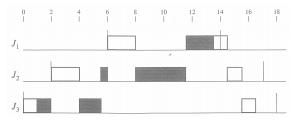

Timing Anomalies due to Resources

Previous example, the critical section of J_3 has length 4

... the critical section of J_3 shortened to 2.5

... but response of J_1 becomes longer!

Mars Pathfinder – The Problem

- Problematic tasks:
 - A bus management task ran frequently with high priority to move data in/out of the bus. If the bus has been locked, then this thread itself had to wait.
 - A meteorological data gathering task ran as an infrequent, low priority thread, and used the bus to publish its data.
 - The bus was also used by a communication task that ran with medium priority.
- Occasionally the communication task (medium priority) was invoked at the precise time when the bus management task (high priority) was blocked by the meteorological data gathering task (low priority) – priority inversion!
- The bus management task was blocked for considerable amount of time by the communication task, which caused a watchdog timer to go off, notice that the bus management task has not been executed for some time, which typically means that something had gone drastically wrong, and initiate a total system reset.

Solutions

Contention for resources causes timing anomalies, priority inversion and deadlock

Several protocols exist to (partially) solve the above problems:

- Non-preemptive CS
- Priority inheritance protocol
- Priority ceiling protocol
- ▶

Terminology:

- A job J_h is (*directly*) *blocked* by a job J_k when
 - the priority of J_k is lower than the priority of J_h and
 - J_k holds a resource R and executes its corresponding critical section
 - J_h requests the resource R

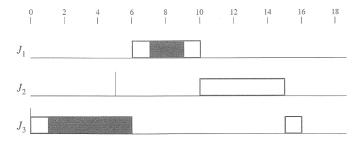

i.e., J_h executed L(R)

In such situation we sometimes say that J_h is blocked by the corresponding critical section of J_k .

The protocol: when a job locks a resource, it is scheduled with priority higher than all other jobs (i.e., is non-preemptive)

Example 28

Jobs J_1 , J_2 , J_3 with release times 2, 5, 0, resp., and with execution times 4, 5, 7, resp.

Non-preemptive Critical Sections – Features

- no deadlock as no job holding a resource is ever preempted
- no unbounded priority inversion:
 - A job J_h can be blocked only at release time. (Indeed, if J_h is not blocked at the release time r_h, it means that no lower priority job holds any resource at r_h. However, no lower priority job can be executed before completion of J_h, and thus no lower priority job may block J_h.)
 - If J_h is blocked at release time, then once the blocking job leaves all (possibly nested) critical sections it is currently in, no lower priority job can block J_h because no other job possesses any resources.
 - It follows that any job can be blocked only once, at release time, blocking time is bounded by duration of one critical section of a lower priority job.

Advantage: very simple; easy to implement both in fixed and dynamic priority; no prior knowledge of resource demands of jobs needed Disadvantage: every job can be blocked by every lower-priority job with a critical section, even if there is no resource conflict

Priority-Inheritance Protocol

Idea: adjust the scheduling priorities of jobs during resource access, to reduce the duration of timing anomalies (As opposed to non-preemptive CS protocol, this time the priority is not always increased to maximum)

Notation:

- assigned priority = priority assigned to a job according to a fixed schedule
- At any time t, each ready job J_k is scheduled and executes at its current priority π_k(t) which may differ from its assigned priority and may vary with time
 - The current priority π_k(t) of a job J_k may be raised to the higher priority π_h(t) of another job J_h
 - In such a situation, the lower-priority job J_k is said to *inherit* the priority of the higher-priority job J_h, and J_k executes at its inherited priority π_h(t)

Priority-Inheritance Protocol

Scheduling rules:

- Jobs are scheduled in a preemptable priority-driven manner according to their current priorities
- At release time, the current priority of a job is equal to its assigned priority
- The current priority remains equal to the assigned priority, except when the priority-inheritance rule is invoked

Priority-inheritance rule:

- When a job J_h becomes blocked on a resource R, the job J_k which blocks J_h inherits the current priority π_h(t) of J_h;
- J_k executes at its inherited priority until it releases R; at that time, the priority of J_k is set to the highest priority of all jobs still blocked by J_k after releasing R. (the resulting priority may still be an inherited priority)

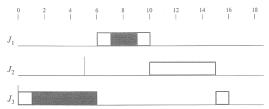

Resource allocation: When a job J requests a resource R at t:

- If R is free, R is allocated to J until J releases it
- ► If *R* is not free, the request is denied and *J* is blocked

(Note that J is only denied R if the resource is held by another job.)

Priority-Inheritance Simple Example

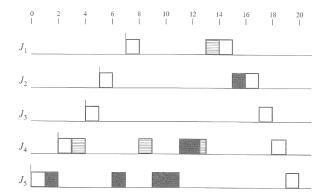

non-preemptive CS:

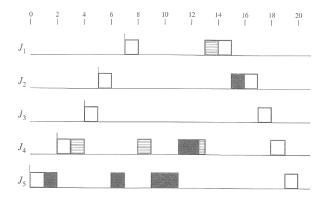

priority-inheritance:

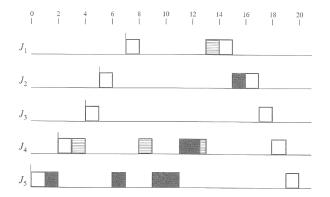

- At 3, J_1 is blocked by J_3 , J_3 inherits priority of J_1
- At 5, J₂ is released but cannot preempt J₃ since the inherited priority of J₃ is higher than the (assigned) priority of J₂

- At 0, J₅ starts executing at priority 5, at 1 it executes L(Black)
- At 2, J_4 preempts J_5 and executes
- At 3, J₄ executes L(Shaded), J₄ continues to execute
- At 4, J₃ preempts J₄; at 5, J₂ preempts J₃
- At 6, J₂ executes L(Black) and is blocked by J₅. Thus J₅ inherits the priority 2 of J₂ and executes

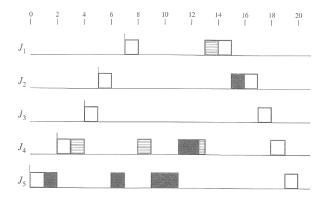

- At 8, J₁ executes L(Shaded) and is blocked by J₄. Thus J₄ inherits the priority 1 of J₁ and executes
- At 9, J₄ executes L(Black) and is blocked by J₅. Thus J₅ inherits the current priority 1 of J₄ and executes

At 11, J₅ executes U(Black), its priority returns to 5 (the priority before locking Black). Now J₄ has the highest priority (1) and executes the Black critical section.

Later, when J_4 executes U(Black), the priority of J_4 remains 1 (since *Shaded* blocks J_1), and J_4 also finishes the *Shaded* critical section (at 13).

- At 13, J₄ executes U(Shaded), its priority returns to 4. J₁ has now the highest priority and executes
- At 15, J₁ completes, J₂ is granted Black and has the highest priority and executes
- At 17, J_2 completes, afterwards J_3 , J_4 , J_5 complete.

Properties of Priority-Inheritance Protocol

- Simple to implement, does not require prior knowledge of resource requirements
- Jobs exhibit two types of "blocking"
 - ► (Direct) blocking due to resource locks i.e., a job J_ℓ locks a resource R, J_h executes L(R) is directly blocked by J_ℓ on R
 - Priority-inheritance "blocking"

i.e., a job J_h is preempted by a lower-priority job that inherited a higher priority

Jobs may exhibit transitive blocking

In the previous example, at 9, J_5 blocks J_4 and J_4 blocks J_1 , hence J_5 inherits the priority of J_1

Deadlock is not prevented

In the previous example, let J_5 request *shaded* at 6.5, then J_4 and J_5 become deadlocked

 Can reduce blocking time (see next slide) compared to non-preemptable CS but does not guarantee to minimize the blocking time

Priority-Inheritance – Blocking Time – Simplified

For every job J_{ℓ} we denote by β_{ℓ}^* the set of all maximal critical sections of the job J_{ℓ} .

(recall that CS are properly nested, maximal CS is the one which is not contained within any other CS)

Theorem 29

Let J_h be a job and let J_{h+1}, \ldots, J_{h+m} be all jobs with the lower priority than J_h . Then J_h can be blocked for at most the duration of one critical section of each β_{ℓ}^* where $\ell \in \{h + 1, \ldots, h + m\}$.

Note that J_h can be blocked by J_ℓ only if J_ℓ is within a critical section of β^{*}_ℓ.

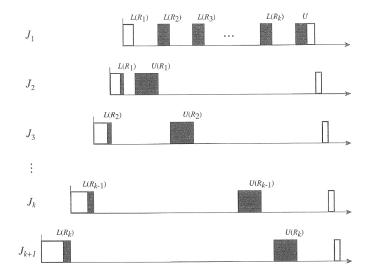

Indeed, if J_ℓ is not in any critical section, then its current priority is equal

to the assigned priority, which is lower than the current priority of J_h .

When J_ℓ leaves the critical section of β^{*}_ℓ, its priority lowers to the assigned priority, and hence cannot be executed before J_h completes.

The blocking time can be bounded from above by summing up maximum lengths of critical sections in all lower priority jobs.

Priority-Inheritance – The Worst Case

 J_1 is blocked for the total duration of all critical sections in all lower priority jobs.

 $\beta_{h,\ell}^*$ = the set of all maximal critical sections of J_ℓ that may block J_h , i.e., which correspond to resources that are (potentially) used by jobs with priorities equal or higher than J_h .

Theorem 30

Let J_h be a job and let J_{h+1}, \ldots, J_{h+m} be all jobs with the lower priority than J_h . Then J_h can be blocked for at most the duration of one critical section of each $\beta_{h,\ell}^*$ where $\ell \in \{h + 1, \ldots, h + m\}$.

- JPL (Jet Propulsion Laboratory) engineers spent hours and hours running the system on a spacecraft replica.
- Early in the morning, after all but one engineer had gone home, the engineer finally reproduced a system reset on the replica.

Solution: Turn the priority inheritance on!

This was done online using a C language interpreter which allowed to execute C functions on-the-fly.

A short code changed a mutex initialization parameter from FALSE to TRUE.

The goal: to further reduce blocking times due to resource contention and to prevent deadlock

 in its basic form priority-ceiling protocol works under the assumption that the priorities of jobs and resources required by all jobs are known apriori

can be extended to dynamic priority (job-level fixed priority), see later

Notation:

- The priority ceiling of any resource R_k is the highest priority of all the jobs that require R_k and is denoted by Π(R_k)
- At any time t, the current priority ceiling Π(t) of the system is equal to the highest priority ceiling of the resources that are in use at the time
- If all resources are free, Π(t) is equal to Ω, a newly introduced priority level that is lower than the lowest priority level of all jobs

The scheduling and priority-inheritance rules are the same as for priority-inheritance protocol

Scheduling rules:

- Jobs are scheduled in a preemptable priority-driven manner according to their current priorities
- At release time, the current priority of a job is equal to its assigned priority
- The current priority remains equal to the assigned priority, except when the priority-inheritance rule is invoked

Priority-inheritance rule:

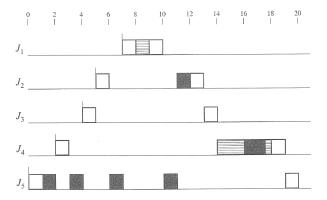

- When job J_h becomes blocked on a resource R, the job J_k which blocks J_h inherits the current priority π_h(t) of J_h;
- J_k executes at its inherited priority until it releases R; at that time, the priority of J_k is set to the highest priority of all jobs still blocked by J_k after releasing R. (which may still be an inherited priority)

Resource allocation rules:

- When a job J requests a resource R held by another job, the request fails and the requesting job blocks
- When a job J requests a resource R at time t, and that resource is free:
 - If J's priority π(t) is strictly higher than current priority ceiling Π(t), R is allocated to J
 - If J's priority π(t) is not higher than Π(t), R is allocated to J only if J is the job holding the resource(s) whose priority ceiling is equal to Π(t), otherwise J is blocked (Note that only one job may hold the resources whose priority ceiling is equal to Π(t))

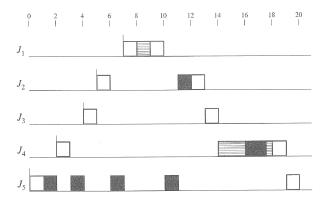

Note that unlike priority-inheritance protocol, the priority-ceiling protocol can deny access to an available resource.

Priority-Ceiling Protocol

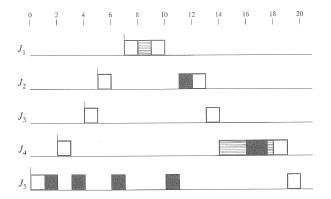

- At 1, $\Pi(t) = \Omega$, J_5 executes L(Black), continues executing
- At 3, Π(t) = 2, J₄ executes L(Shaded); because the ceiling of the system Π(t) is higher than the current priority of J₄, job J₄ is blocked, J₅ inherits J₄'s priority and executes at priority 4
- At 4, J₃ preempts J₅; at 5, J₂ preempts J₃. At 6, J₂ requests Black and is directly blocked by J₅. Consequently, J₅ inherits priority 2 and executes until preempted by J₁

Priority-Ceiling Protocol

- At 8, J₁ executes L(Shaded), its priority is higher than Π(t) = 2, its request is granted and J₁ executes; at 9, J₁ executes U(Shaded) and at 10 completes
- At 11, J₅ releases Black and its priority drops to 5; J₂ becomes unblocked, is allocated Black and executes

Priority-Ceiling Protocol

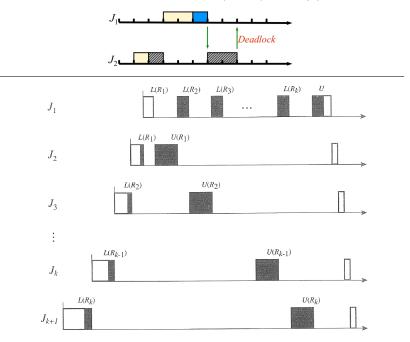

- At 14, J_2 and J_3 complete, J_4 is granted *Shaded* (because its priority is higher than $\Pi(t) = \Omega$) and executes
- At 16, J_4 executes L(Black) which is free, the priority of J_4 is not higher than $\Pi(16) = 1$ but J_4 is the job holding the resource whose priority ceiling is equal to $\Pi(16)$. Thus J_4 gets *Black*, continues to execute; the rest is clear

Theorem 31

Assume a system of preemptable jobs with fixed assigned priorities. Then

- deadlock may never occur,
- a job can be blocked for at most the duration of one critical section.

These situations cannot occur with priority ceiling protocol:

Differences between the priority-inheritance and priority-ceiling

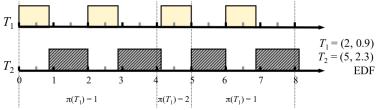

- Priority-inheritance is greedy, while priority ceiling is not The priority-ceiling protocol may withhold access to a free resource, i.e., a job can be prevented from execution by a lower-priority job which does not hold the requested resource – avoidance "blocking"
- The priority ceiling protocol forces a fixed order onto resource accesses thus eliminating deadlock

Resources in Dynamic Priority Systems

The priority ceiling protocol assumes fixed and known priorities

In a dynamic priority system, the priorities of the periodic tasks change over time, while the set of resources is required by each task remains constant

As a consequence, the priority ceiling of each resource changes over time

What happens if T_1 uses resource X, but T_2 does not?

Priority ceiling of X is 1 for 0 ≤ t ≤ 4, becomes 2 for 4 ≤ t ≤ 5, etc. even though the set of resources is required by the tasks remains unchanged

Resources in Dynamic Priority Systems

- If a system is job-level fixed priority, but task-level dynamic priority, a priority ceiling protocol can still be applied
 - Each job in a task has a fixed priority once it is scheduled, but may be scheduled at different priority to other jobs in the task (e.g. EDF)
 - Update the priority ceilings of all resources each time a new job is introduced; use until updated on next job release
- Has been proven to prevent deadlocks and no job is ever blocked for longer than the length of one critical section
 - But: very inefficient, since priority ceilings updated frequently
 - May be better to use priority inheritance, accept longer blocking

Schedulability Tests with Resources

How to adjust schedulability tests?

Add the blocking times to execution times of jobs; then run the test as normal

The blocking time b_i of a job J_i can be determined for all three protocols:

- ► non-preemptable CS ⇒ b_i is bounded by the maximum length of a critical section in lower priority jobs
- ► priority-inheritance ⇒ b_i is bounded by the total length of the *m* longest critical sections where *m* is the number of jobs that may block J_i

(For a more precise formulation see Theorem 30)

► priority-ceiling ⇒ b_i is bounded by the maximum length of a critical section

Source: Zhang et al. Priority Inheritance Protocol Proved Correct. ITP 2012

Two advantages of PIP are that it is deterministic and that increasing the priority of a thread can be performed dynamically by the scheduler. This is in contrast to *Priority Ceiling* [24], another solution to the Priority Inversion problem, which requires static analysis of the program in order to prevent Priority Inversion, and also in contrast to the approach taken in the Windows NT scheduler, which avoids this problem by randomly boosting the priority of ready low-priority threads (see for instance [2]). However, there has also been strong criticism against PIP.

Source: Zhang et al. Priority Inheritance Protocol Proved Correct. ITP 2012

Two advantages of PIP are that it is deterministic and that increasing the priority of a thread can be performed dynamically by the scheduler. This is in contrast to *Priority Ceiling* [24], another solution to the Priority Inversion problem, which requires static analysis of the program in order to prevent Priority Inversion, and also in contrast to the approach taken in the Windows NT scheduler, which avoids this problem by randomly boosting the priority of ready low-priority threads (see for instance [2]). However, there has also been strong criticism against PIP.

Though, most criticism against PIP centres around unreliable implementations and PIP being too complicated and too inefficient. For example, Yodaiken writes in [30]:

"Priority inheritance is neither efficient nor reliable. Implementations are either incomplete (and unreliable) or surprisingly complex and intrusive."

He suggests avoiding PIP altogether by designing the system so that no priority inversion may happen in the first place. However, such ideal designs may not always be achievable in practice.

In our opinion, there is clearly a need for investigating correct algorithms for PIP. A few specifications for PIP exist (in informal English) and also a few high-level descriptions of implementations (e.g. in the textbooks [15, Section 12.3.1] and [26, Section 5.6.5]), but they help little with actual implementations. That this is a problem in practice is proved by an email by Baker, who wrote on 13 July 2009 on the Linux Kernel mailing list:

"I observed in the kernel code (to my disgust), the Linux PIP implementation is a nightmare: extremely heavy weight, involving maintenance of a full wait-for graph, and requiring updates for a range of events, including priority changes and interruptions of wait operations."

In our opinion, there is clearly a need for investigating correct algorithms for PIP. A few specifications for PIP exist (in informal English) and also a few high-level descriptions of implementations (e.g. in the textbooks [15, Section 12.3.1] and [26, Section 5.6.5]), but they help little with actual implementations. That this is a problem in practice is proved by an email by Baker, who wrote on 13 July 2009 on the Linux Kernel mailing list:

"I observed in the kernel code (to my disgust), the Linux PIP implementation is a nightmare: extremely heavy weight, involving maintenance of a full wait-for graph, and requiring updates for a range of events, including priority changes and interruptions of wait operations."

While [13, 14, 15, 20, 24, 25] are the only formal publications we have found that specify the incorrect behaviour, it seems also many informal descriptions of the PIP protocol overlook the possibility that another high-priority process might wait for a low-priority process to finish. A notable exception is the textbook [3], which gives the correct behaviour of resetting the priority of a thread to the highest remaining priority of the threads it blocks. This textbook also gives an informal proof for the correctness of PIP in the style of Sha et al. Unfortunately, this informal proof is too vague to be useful for formalising the correctness of PIP and the specification leaves out nearly all details in order to implement PIP efficiently.

Real-Time Scheduling

Multiprocessor Real-Time Systems

- Many embedded systems are composed of many processors (control systems in cars, aircraft, industrial systems etc.)
- Today most processors in computers have multiple cores The main reason is that increasing frequency of a single processor is no more feasible (mostly due to power consumption problems, growing leakage currents, memory problems etc.)

Applications must be developed specifically for multiprocessor systems.

In case of real-time systems, multiple processors bring serious difficulties concerning correctness, predictability and efficiency.

The "root of all evil" in global scheduling: (Liu, 1969)

Few of the results obtained for a single processor generalize directly to the multiple processor case; bringing in additional processors adds a new dimension to the scheduling problem. The simple fact that a task can use only one processor even when several processors are free at the same time adds a surprising amount of difficulty to the scheduling of multiple processors. A job is a unit of work that is scheduled and executed by a system

(Characterised by the release time r_i , execution time e_i and deadline d_i)

- A task is a set of related jobs which jointly provide some system function
- Jobs execute on processors

In this lecture we consider *m* processors

Jobs may use some (shared) passive resources

Schedule

Schedule assigns, in every time instant, processors and resources to jobs.

A schedule is *feasible* if *all jobs with hard real-time constraints* complete before their deadlines.

Schedule

Schedule assigns, in every time instant, processors and resources to jobs.

A schedule is *feasible* if *all jobs with hard real-time constraints* complete before their deadlines.

A set of jobs is *schedulable* if there is a feasible schedule for the set.

A scheduling algorithm is optimal if it always produces a feasible schedule whenever such a schedule exists. (and if a cost function is given, minimizes the cost)

Schedule

Schedule assigns, in every time instant, processors and resources to jobs.

A schedule is *feasible* if *all jobs with hard real-time constraints* complete before their deadlines.

A set of jobs is *schedulable* if there is a feasible schedule for the set.

A scheduling algorithm is optimal if it always produces a feasible schedule whenever such a schedule exists. (and if a cost function is given, minimizes the cost)

We also consider *online* scheduling algorithms that do not use any knowlede about jobs that will be released in the future but are given a complete information about jobs that have been released. (e.g. EDF is online)

- Identical processors: All processors identical, have the same computing power
- Uniform processors: Each processor is characterized by its own computing capacity κ, completes κt units of execution after t time units
- Unrelated processors: There is an execution rate ρ_{ij} associated with each job-processor pair (J_i, P_j) so that J_i completes ρ_{ij}t units of execution by executing on P_j for t time units

In addition, cost of communication can be included etc.

Assumptions – Priority Driven Scheduling

Throughout this lecture we assume:

- Unless otherwise stated, consider *m identical* processors
- Jobs can be preempted at any time and never suspend themselves
- Context switch overhead is negligibly small
 - i.e. assumed to be zero
- There is an unlimited number of priority levels
- For simplicity, we assume independent jobs that do not contend for resources

Unless otherwise stated, we assume that scheduling decisions take place only when a job is released, or completed. Multiprocessor scheduling attempts to solve two problems:

- the allocation problem, i.e., on which processor a given job executes
- the priority problem, i.e., when and in what order the jobs execute

Issues

What results from single processor scheduling remain valid in multiprocessor setting?

- Are there simple optimal scheduling algorithms?
- Are there optimal online scheduling algorithms (i.e. those that do not know what jobs come in future)
- Are there efficient tests for schedulability?

Issues

What results from single processor scheduling remain valid in multiprocessor setting?

- Are there simple optimal scheduling algorithms?
- Are there optimal online scheduling algorithms (i.e. those that do not know what jobs come in future)
- Are there efficient tests for schedulability?

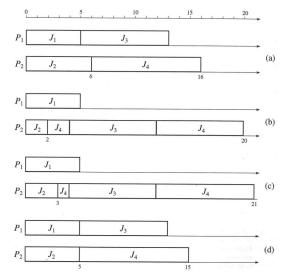

In this lecture we consider:

- Individual jobs
- Periodic tasks

Start with *n* individual jobs $\{J_1, \ldots, J_n\}$

Individual Jobs – Timing Anomalies

Priority order: $J_1 \sqsupset \cdots \sqsupset J_4$; execute greedily on available processors

EDF on *m* identical processors: At any time instant, jobs with the earliest absolute deadlines are executed on available processors. (Recall: no job can be executed on more than one processor at a given time!)

Is this optimal?

EDF on *m* identical processors: At any time instant, jobs with the earliest absolute deadlines are executed on available processors. (Recall: no job can be executed on more than one processor at a given time!)

Is this optimal? NO!

Example:

 J_1, J_2, J_3 where

▶ $r_i = 0$ for $i \in \{1, 2, 3\}$

•
$$e_1 = e_2 = 1$$
 and $e_3 = 5$

•
$$d_1 = 1, d_2 = 2, d_3 = 5$$

2 processors.

No optimal online scheduler exists for the following jobs on two processors:

No optimal online scheduler exists for the following jobs on two processors:

Consider three jobs J_1 , J_2 , J_3 are released at time 0 with the following parameters:

•
$$e_1 = e_2 = 2$$
 and $e_3 = 4$

•
$$d_1 = d_2 = 4$$
 and $d_3 = 8$

No optimal online scheduler exists for the following jobs on two processors:

Consider three jobs J_1 , J_2 , J_3 are released at time 0 with the following parameters:

•
$$e_1 = e_2 = 2$$
 and $e_3 = 4$

•
$$d_1 = d_2 = 4$$
 and $d_3 = 8$

Depending on scheduling in [0, 2], new jobs J_4 , J_5 are released at, or after 2 as follows:

If J₃ is executed in [0, 2], then at 2 release J₄, J₅ with d₄ = d₅ = 4 and e₄ = e₅ = 2.

No optimal online scheduler exists for the following jobs on two processors:

Consider three jobs J_1 , J_2 , J_3 are released at time 0 with the following parameters:

•
$$e_1 = e_2 = 2$$
 and $e_3 = 4$

•
$$d_1 = d_2 = 4$$
 and $d_3 = 8$

Depending on scheduling in [0, 2], new jobs J_4 , J_5 are released at, or after 2 as follows:

- If J₃ is executed in [0, 2], then at 2 release J₄, J₅ with d₄ = d₅ = 4 and e₄ = e₅ = 2.
- ▶ If J_3 is not executed in [0, 2], then at 4 release J_4 , J_5 with $d_4 = d_5 = 8$ and $e_4 = e_5 = 4$.

No optimal online scheduler exists for the following jobs on two processors:

Consider three jobs J_1 , J_2 , J_3 are released at time 0 with the following parameters:

•
$$e_1 = e_2 = 2$$
 and $e_3 = 4$

•
$$d_1 = d_2 = 4$$
 and $d_3 = 8$

Depending on scheduling in [0, 2], new jobs J_4 , J_5 are released at, or after 2 as follows:

- If J₃ is executed in [0, 2], then at 2 release J₄, J₅ with d₄ = d₅ = 4 and e₄ = e₅ = 2.
- ▶ If J_3 is not executed in [0, 2], then at 4 release J_4 , J_5 with $d_4 = d_5 = 8$ and $e_4 = e_5 = 4$.

In either case the schedule produced is not feasible. However, if the scheduler is given either of the sets $\{J_1, \ldots, J_5\}$ at the beginning, then there is a feasible schedule.

Individual Jobs – Speedup Helps(?)

Theorem 32

If a set of jobs is feasible on m identical processors, then the same set of jobs will be scheduled to meet all deadlines by EDF on identical processors in which the individual processors are $(2 - \frac{1}{m})$ times as fast as in the original system.

Theorem 32

If a set of jobs is feasible on m identical processors, then the same set of jobs will be scheduled to meet all deadlines by EDF on identical processors in which the individual processors are $(2 - \frac{1}{m})$ times as fast as in the original system.

The result is tight for EDF (assuming dynamic job priority):

Theorem 33

There are sets of jobs that can be feasibly scheduled on m identical processors but EDF cannot schedule them on m processors that are only $(2 - \frac{1}{m} - \varepsilon)$ faster for every $\varepsilon > 0$.

Theorem 32

If a set of jobs is feasible on m identical processors, then the same set of jobs will be scheduled to meet all deadlines by EDF on identical processors in which the individual processors are $(2 - \frac{1}{m})$ times as fast as in the original system.

The result is tight for EDF (assuming dynamic job priority):

Theorem 33

There are sets of jobs that can be feasibly scheduled on m identical processors but EDF cannot schedule them on m processors that are only $(2 - \frac{1}{m} - \varepsilon)$ faster for every $\varepsilon > 0$.

... there are also general lower bounds for online algorithms:

Theorem 34

There are sets of jobs that can be feasibly scheduled on *m* (here *m* is even) identical processors but **no online** algorithm can schedule them on *m* processors that are only $(1 + \varepsilon)$ faster for every $\varepsilon < \frac{1}{5}$.

[Optimal Time-Critical Scheduling Via Resource Augmentation, Phillips et al, STOC 1997]

Consider fixed number, *n*, of *independent periodic* tasks $\mathcal{T} = \{T_1, \dots, T_n\}$

i.e. there is no dependency relation among jobs

- Unless otherwise stated, assume no phase and deadlines equal to periods
- Ignore aperiodic tasks
- No sporadic tasks unless otherwise stated

Consider fixed number, *n*, of *independent periodic* tasks $\mathcal{T} = \{T_1, \dots, T_n\}$

i.e. there is no dependency relation among jobs

- Unless otherwise stated, assume no phase and deadlines equal to periods
- Ignore aperiodic tasks
- No sporadic tasks unless otherwise stated

Utilization u_i of a periodic task T_i with period p_i and execution time e_i is defined by $u_i := e_i/p_i$ u_i is the fraction of time a periodic task with period p_i and execution time e_i keeps a processor busy

Consider fixed number, *n*, of *independent periodic* tasks $\mathcal{T} = \{T_1, \dots, T_n\}$

i.e. there is no dependency relation among jobs

- Unless otherwise stated, assume no phase and deadlines equal to periods
- Ignore aperiodic tasks
- No sporadic tasks unless otherwise stated

Utilization u_i *of a periodic task* T_i with period p_i and execution time e_i is defined by $u_i := e_i/p_i$ u_i is the fraction of time a periodic task with period p_i and execution time e_i keeps a processor busy

Total utilization $U^{\mathcal{T}}$ of a set of tasks $\mathcal{T} = \{T_1, \dots, T_n\}$ is defined as the sum of utilizations of all tasks of \mathcal{T} , i.e. by $U^{\mathcal{T}} := \sum_{i=1}^n u_i$

Consider fixed number, *n*, of *independent periodic* tasks $\mathcal{T} = \{T_1, \ldots, T_n\}$

i.e. there is no dependency relation among jobs

- Unless otherwise stated, assume no phase and deadlines equal to periods
- Ignore aperiodic tasks
- No sporadic tasks unless otherwise stated

Utilization u_i of a periodic task T_i with period p_i and execution time e_i is defined by $u_i := e_i/p_i$ u_i is the fraction of time a periodic task with period p_i and execution time e_i keeps a processor busy

Total utilization $U^{\mathcal{T}}$ of a set of tasks $\mathcal{T} = \{T_1, \dots, T_n\}$ is defined as the sum of utilizations of all tasks of \mathcal{T} , i.e. by $U^{\mathcal{T}} := \sum_{i=1}^n u_i$

Given a scheduling algorithm *ALG*, the schedulable utilization U_{ALG} of *ALG* is the maximum number *U* such that for all \mathcal{T} : $U_{\mathcal{T}} \leq U$ implies \mathcal{T} is schedulable by *ALG*.

Multiprocessor Scheduling Taxonomy

Allocation (migration type)

- No migration: each task is allocated to a processor
- (Task-level migration: jobs of a task may execute on different processors; however, each job is assigned to a single processor)
- Job-level migration: A single job can migrate and execute on different processors

(however, parallel execution of one job is not permitted and migration takes place only when the job is rescheduled)

Multiprocessor Scheduling Taxonomy

Allocation (migration type)

- No migration: each task is allocated to a processor
- (Task-level migration: jobs of a task may execute on different processors; however, each job is assigned to a single processor)
- Job-level migration: A single job can migrate and execute on different processors

(however, parallel execution of one job is not permitted and migration takes place only when the job is rescheduled)

Priority type

- Fixed task-level priority (e.g. RM)
- Fixed job-level priority (e.g. EDF)
- (Dynamic job-level priority)

Multiprocessor Scheduling Taxonomy

Allocation (migration type)

- Fixed job-level priority (e.g. EDF)
- (Dynamic job-level priority)

Partitioned scheduling = No migration **Global** scheduling = job-level migration

Consider *m* processors and m + 1 tasks $\mathcal{T} = \{T_1, \dots, T_{m+1}\}$, each $T_i = (2L - 1, L)$.

Consider *m* processors and m + 1 tasks $\mathcal{T} = \{T_1, \dots, T_{m+1}\}$, each $T_i = (2L - 1, L)$.

Then $U_{\mathcal{T}} = \sum_{i=1}^{m+1} L/(2L-1) = (m+1)(L/(2L-1)) = (m+1)/2 \cdot L/(L-1)$ For very large *L*, this number is close to (m+1)/2.

Consider *m* processors and m + 1 tasks $\mathcal{T} = \{T_1, \dots, T_{m+1}\}$, each $T_i = (2L - 1, L)$.

Then $U_{\mathcal{T}} = \sum_{i=1}^{m+1} L/(2L-1) = (m+1)(L/(2L-1)) = (m+1)/2 \cdot L/(L-1)$ For very large *L*, this number is close to (m+1)/2.

The set $\ensuremath{\mathcal{T}}$ is not schedulable using any fixed job-level priority algorithm.

In other words, the schedulable utilization of fixed job-level priority algorithms is at most (m + 1)/2, i.e., half of the processors capacity.

Consider *m* processors and m + 1 tasks $\mathcal{T} = \{T_1, \dots, T_{m+1}\}$, each $T_i = (2L - 1, L)$.

Then $U_{\mathcal{T}} = \sum_{i=1}^{m+1} L/(2L-1) = (m+1)(L/(2L-1)) = (m+1)/2 \cdot L/(L-1)$ For very large *L*, this number is close to (m+1)/2.

The set \mathcal{T} is not schedulable using any *fixed job-level* priority algorithm.

In other words, the schedulable utilization of fixed job-level priority algorithms is at most (m + 1)/2, i.e., half of the processors capacity.

There are variants of EDF achieving this bound (see later slides).

Most algorithms up to the end of 1990s based on *partitioned scheduling*

no migration

From the end of 1990s, many results concerning *global* scheduling

job-level migration

The task-level migration has not been much studied, so it is not covered in this lecture.

We consider fixed job-level priority (e.g., EDF) and fixed task-level priority (e.g., RM). As before, we ignore dynamic job-level priority.

Partitioned Scheduling & Fixed Job-Level Priority

The algorithm proceeds in two phases:

- 1. Allocate tasks to processors, i.e., partition the set of tasks into m possibly empty modules M_1, \ldots, M_m
- Schedule tasks of each M_i on the processor i according to a given single processor algorithm

The quality of task assignment is determined by the number of assigned processors

Partitioned Scheduling & Fixed Job-Level Priority

The algorithm proceeds in two phases:

- 1. Allocate tasks to processors, i.e., partition the set of tasks into m possibly empty modules M_1, \ldots, M_m
- Schedule tasks of each M_i on the processor i according to a given single processor algorithm

The quality of task assignment is determined by the number of assigned processors

- Use EDF to schedule modules
- Suffices to test whether the total utilization of each module is ≤ 1 (or, possibly, ≤ Û where Û < 1 in order to accomodate aperiodic jobs ...)</p>

Partitioned Scheduling & Fixed Job-Level Priority

The algorithm proceeds in two phases:

- 1. Allocate tasks to processors, i.e., partition the set of tasks into m possibly empty modules M_1, \ldots, M_m
- Schedule tasks of each M_i on the processor i according to a given single processor algorithm

The quality of task assignment is determined by the number of assigned processors

- Use EDF to schedule modules
- Suffices to test whether the total utilization of each module is ≤ 1 (or, possibly, ≤ Û where Û < 1 in order to accomodate aperiodic jobs ...)</p>

A simple *uniform-size bin-packing problem* is polynomially reducible to finding an optimal schedule. So the latter is NP-hard.

Similarly, we may use RM for fixed task-level priorities (total utilization in modules $\leq \log 2$, etc.)

- All ready jobs are kept in a global queue
- When selected for execution, a job can be assigned to any processor
- When preempted, a job goes to the global queue (i.e., forgets on which processor it executed)

Global Scheduling – Fixed Job-Level Priority

Dhall's effect:

- Consider m > 1 processors
- ► Let ε > 0
- Consider a set of tasks $\mathcal{T} = \{T_1, \ldots, T_m, T_{m+1}\}$ such that

•
$$T_i = (1, 2\varepsilon)$$
 for $1 \le i \le m$

•
$$T_{m+1} = (1 + \varepsilon, 1)$$

Global Scheduling – Fixed Job-Level Priority

Dhall's effect:

- Consider m > 1 processors
- ► Let ε > 0
- Consider a set of tasks $\mathcal{T} = \{T_1, \ldots, T_m, T_{m+1}\}$ such that

•
$$T_i = (1, 2\varepsilon)$$
 for $1 \le i \le m$

- ► $T_{m+1} = (1 + \varepsilon, 1)$
- \mathcal{T} is schedulable
- Stadnard EDF and RM schedules are not feasible (whiteb.)

Global Scheduling – Fixed Job-Level Priority

Dhall's effect:

- Consider m > 1 processors
- ► Let ε > 0
- Consider a set of tasks $\mathcal{T} = \{T_1, \ldots, T_m, T_{m+1}\}$ such that

•
$$T_i = (1, 2\varepsilon)$$
 for $1 \le i \le m$

- $T_{m+1} = (1 + \varepsilon, 1)$
- \mathcal{T} is schedulable
- Stadnard EDF and RM schedules are not feasible (whiteb.)

However,

$$U_{\mathcal{T}} = m \frac{2\varepsilon}{1} + \frac{1}{1+\varepsilon}$$

which means that for small ε the utilization $U_{\mathcal{T}}$ is close to 1 (i.e., $U_{\mathcal{T}}/m$ is very small for m >> 0 processors)

Qustion: What is the maximum schedulable utilization of EDF on *m* processors?

Note that RM and EDF only account for task periods and ignore the execution time!

- Note that RM and EDF only account for task periods and ignore the execution time!
- (Partial) Solution: Dhall's effect can be avoided by giving high priority to tasks with high utilization

Then in the previous example, T_{m+1} is executed whenever it comes and the other tasks are assigned to the remaining processors – produces a feasible schedule Apparently there is a problem with long jobs due to Dhall's effect. There is an improved version of EDF called EDF-US(1/2) which

- assigns the highest priority to tasks with $u_i \ge 1/2$
- assigns priorities to the rest according to deadlines

which reaches the generic schedulable utilization bound (m + 1)/2.

Advantages of the global scheduling:

- Load is automatically balanced
- Better average response time (follows from queueing theory)

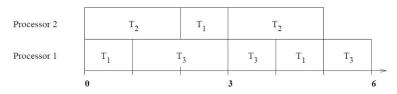

Disadvantages of the global scheduling:

- Problems caused by migration (e.g. increased cache misses)
- Schedulability tests more difficult (active area of research)

Is either of the approaches better from the schedulability standpoint?

There are sets of tasks schedulable only with global scheduler:

▶ $T = \{T_1, T_2, T_3\}$ where $T_1 = (2, 1), T_2 = (3, 2), T_3 = (3, 2),$ can be scheduled using a global scheduler:

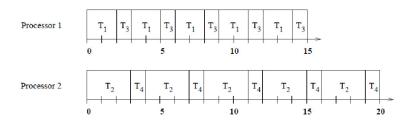

No feasible partitioned schedule exists, always at least one processor gets tasks with total utilization higher than 1.

Partitioned Beats Global

There are task sets that can be scheduled only with partitioned scheduler (assuming fixed task-level priority assignment):

► $\mathcal{T} = \{T_1, \dots, T_4\}$ where $T_1 = (3, 2), T_2 = (4, 3), T_3 = (15, 5), T_4 = (20, 5),$ can be scheduled using a fixed task-level priority partitioned schedule:

Global scheduling (fixed job-level priority): There are 9 jobs released in the interval [0, 12). Any of the 9! possible priority assignments leads to a deadline miss.

Optimal Algorithm?

There IS an optimal algorithm in the case of job-level migration & dynamic job-level priority. However, the algorithm is *clock driven*.

The *priority fair* (PFair) algorithm is optimal for periodic systems with deadlines equal to periods

Optimal Algorithm?

There IS an optimal algorithm in the case of job-level migration & dynamic job-level priority. However, the algorithm is *clock driven*.

The *priority fair* (PFair) algorithm is optimal for periodic systems with deadlines equal to periods

Idea (of PFair): In any interval (0, t] jobs of a task T_i with utilization u_i execute for amount of time W so that $u_it - 1 < W < u_it + 1$ (Here every parameter is assumed to be a natural number)

This is achieved by cutting time into small quanta and scheduling jobs in these quanta so that the execution times are always (more or less) in proportion.

Optimal Algorithm?

There IS an optimal algorithm in the case of job-level migration & dynamic job-level priority. However, the algorithm is *clock driven*.

The *priority fair* (PFair) algorithm is optimal for periodic systems with deadlines equal to periods

Idea (of PFair): In any interval (0, t] jobs of a task T_i with utilization u_i execute for amount of time W so that $u_it - 1 < W < u_it + 1$ (Here every parameter is assumed to be a natural number)

This is achieved by cutting time into small quanta and scheduling jobs in these quanta so that the execution times are always (more or less) in proportion.

There are other optimal algorithms, all of them suffer from a large number of preemptions/migrations.

No optimal algorithms are known for more general settings: deadlines bounded by periods, arbitrary deadlines.

Recall, that no optimal on-line scheduling possible

Real-Time Scheduling

Scheduling of Reactive Systems

Clock-Driven Scheduling

Current Assumptions

Fixed number, *n*, of periodic tasks T_1, \ldots, T_n

Current Assumptions

- ▶ Fixed number, *n*, of periodic tasks *T*₁,..., *T*_n
- Parameters of periodic tasks are known a priori
 - Execution time e_{i,k} of each job J_{i,k} in a task T_i is fixed
 - For a job $J_{i,k}$ in a task T_i we have

•
$$r_{i,1} = \varphi_i = 0$$
 (i.e., synchronized)

►
$$r_{i,k} = r_{i,k-1} + p_i$$

Current Assumptions

- ▶ Fixed number, *n*, of periodic tasks *T*₁,..., *T*_n
- Parameters of periodic tasks are known a priori
 - Execution time $e_{i,k}$ of each job $J_{i,k}$ in a task T_i is fixed
 - For a job $J_{i,k}$ in a task T_i we have
 - $r_{i,1} = \varphi_i = 0$ (i.e., synchronized)

$$r_{i,k} = r_{i,k-1} + p_i$$

- We allow aperiodic tasks
 - assume that the system maintains a single queue for jobs of aperiodic tasks
 - Whenever the processor is available for aperiodic tasks, the job at the head of this queue is executed
- We treat sporadic tasks later

Abuse of notation: Periodic, aperiodic, sporadic jobs are jobs of periodic, aperiodic, sporadic tasks, respectively.

Static, Clock-Driven Scheduler

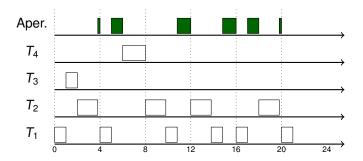

- Construct a static schedule offline
 - The schedule specifies exactly when each job executes
 - The amount of time allocated to every job is equal to its execution time
 - The schedule repeats each hyperperiod
 - i.e. it suffices to compute the schedule up to hyperperiod

- Construct a static schedule offline
 - The schedule specifies exactly when each job executes
 - The amount of time allocated to every job is equal to its execution time
 - The schedule repeats each hyperperiod i.e. it suffices to compute the schedule up to hyperperiod
- Can use complex algorithms offline
 - Runtime of the scheduling algorithm is not relevant
 - Can compute a schedule that optimizes some characteristics of the system
 e.g. a schedule where the idle periods are nearly periodic (useful

to accommodate aperiodic jobs)

Example

 $T_1 = (4, 1), T_2 = (5, 1.8), T_3 = (20, 1), T_4 = (20, 2)$ Hyperperiod H = 20

- Store pre-computed schedule as a table
 - Each entry $(t_k, T(t_k))$ gives
 - a decision time t_k
 - scheduling decision T(t_k) which is either a task to be executed, or idle (denoted by I)

- Store pre-computed schedule as a table
 - Each entry $(t_k, T(t_k))$ gives
 - a decision time t_k
 - scheduling decision T(t_k) which is either a task to be executed, or idle (denoted by I)
- The system creates all tasks that are to be executed:
 - Allocates memory for the code and data
 - Brings the code into memory

- Store pre-computed schedule as a table
 - Each entry (t_k, T(t_k)) gives
 - a decision time t_k
 - scheduling decision T(t_k) which is either a task to be executed, or idle (denoted by I)
- The system creates all tasks that are to be executed:
 - Allocates memory for the code and data
 - Brings the code into memory
- Scheduler sets the hardware timer to interrupt at the first decision time $t_0 = 0$

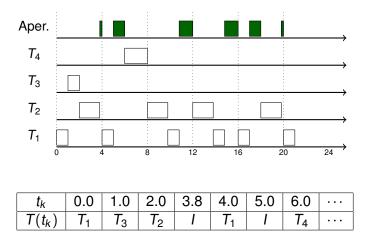

- Store pre-computed schedule as a table
 - Each entry (t_k, T(t_k)) gives
 - a decision time t_k
 - scheduling decision T(t_k) which is either a task to be executed, or idle (denoted by I)
- The system creates all tasks that are to be executed:
 - Allocates memory for the code and data
 - Brings the code into memory
- Scheduler sets the hardware timer to interrupt at the first decision time $t_0 = 0$
- On receipt of an interrupt at t_k:
 - Scheduler sets the timer interrupt to t_{k+1}
 - If previous task overrunning, handle failure
 - If T(t_k) = I and aperiodic job waiting, start executing it
 - Otherwise, start executing the next job in $T(t_k)$

k	t_k	$T(t_k)$
0	0.0	T_1
1	1.0	T_3
2	2.0	T_2
3	3.8	Ι
4	4.0	T_1
5	5.0	Ι
6	6.0	T_4
7	8.0	T_2
8	9.8	T_1
9	10.8	Ι
10	12.0	T_2
11	13.8	T_1
12	14.8	Ι
13	17.0	T_1
14	17.0	Ι
15	18.0	T_2
16	19.8	Ι

Example

$$T_1 = (4, 1), T_2 = (5, 1.8), T_3 = (20, 1), T_4 = (20, 2)$$

Hyperperiod H = 20

- Arbitrary table-driven cyclic schedules flexible, but inefficient
 - Relies on accurate timer interrupts, based on execution times of tasks
 - High scheduling overhead

- Arbitrary table-driven cyclic schedules flexible, but inefficient
 - Relies on accurate timer interrupts, based on execution times of tasks
 - High scheduling overhead
- Easier to implement if a structure is imposed
 - Make scheduling decisions at periodic intervals (frames) of length f
 - Execute a fixed list of jobs within each frame; no preemption within frames

- Arbitrary table-driven cyclic schedules flexible, but inefficient
 - Relies on accurate timer interrupts, based on execution times of tasks
 - High scheduling overhead
- Easier to implement if a structure is imposed
 - Make scheduling decisions at periodic intervals (frames) of length f
 - Execute a fixed list of jobs within each frame; no preemption within frames
- Gives two benefits:
 - Scheduler can easily check for overruns and missed deadlines at the end of each frame.
 - Can use a periodic clock interrupt, rather than programmable timer.

Frame Based Scheduling – Cyclic Executive

- Modify previous table-driven scheduler to be frame based
- Table that drives the scheduler has F entries, where F = H/f
 - The k-th entry L(k) lists the names of the jobs that are to be scheduled in frame k (L(k) is called scheduling block)
 - Each job is implemented by a procedure

Frame Based Scheduling – Cyclic Executive

- Modify previous table-driven scheduler to be frame based
- Table that drives the scheduler has F entries, where F = H/f
 - The k-th entry L(k) lists the names of the jobs that are to be scheduled in frame k (L(k) is called scheduling block)
 - Each job is implemented by a procedure
- Cyclic executive executed by the clock interrupt that signals the start of a frame:
 - If an aperiodic job is executing, preempts it; if a periodic overruns, handles the overrun
 - Determines the appropriate scheduling block for this frame
 - Executes the jobs in the scheduling block
 - Executes jobs from the head of the aperiodic job queue for the remainder of the frame

Frame Based Scheduling – Cyclic Executive

- Modify previous table-driven scheduler to be frame based
- Table that drives the scheduler has F entries, where F = H/f
 - The k-th entry L(k) lists the names of the jobs that are to be scheduled in frame k (L(k) is called scheduling block)
 - Each job is implemented by a procedure
- Cyclic executive executed by the clock interrupt that signals the start of a frame:
 - If an aperiodic job is executing, preempts it; if a periodic overruns, handles the overrun
 - Determines the appropriate scheduling block for this frame
 - Executes the jobs in the scheduling block
 - Executes jobs from the head of the aperiodic job queue for the remainder of the frame
- Less overhead than pure table driven cyclic scheduler, since only interrupted on frame boundaries, rather than on each job

Frame Based Scheduling – Frame Size

How to choose the frame length?

(Assume that periods are in ${\mathbb N}$ and choose frame sizes in ${\mathbb N}.)$

1. Necessary condition for avoiding preemption of jobs is

 $f \geq \max_i e_i$

(i.e. we want each job to have a chance to finish within a frame)

Frame Based Scheduling – Frame Size

How to choose the frame length?

(Assume that periods are in ${\mathbb N}$ and choose frame sizes in ${\mathbb N}.)$

1. Necessary condition for avoiding preemption of jobs is

 $f \geq \max_i e_i$

(i.e. we want each job to have a chance to finish within a frame)

2. To minimize the number of entries in the cyclic schedule, the hyper-period should be an integer multiple of the frame size, i.e.

 $\exists i : p_i \mod f = 0$

Frame Based Scheduling – Frame Size

How to choose the frame length?

(Assume that periods are in ${\mathbb N}$ and choose frame sizes in ${\mathbb N}.)$

1. Necessary condition for avoiding preemption of jobs is

 $f \geq \max_{i} e_{i}$

(i.e. we want each job to have a chance to finish within a frame)

2. To minimize the number of entries in the cyclic schedule, the hyper-period should be an integer multiple of the frame size, i.e.

 $\exists i: p_i \mod f = 0$

3. To allow scheduler to check that jobs complete by their deadline, at least one frame should lie between release time of a job and its deadline, which is equivalent to

 $\forall i: 2 * f - gcd(p_i, f) \leq D_i$

All three constraints should be satisfied.

Frame Based Scheduling – Frame Size – Example

1. $f \ge \max_i e_i$ **2.** $\exists i : p_i \mod f = 0$ **3.** $\forall i : 2 * f - gcd(p_i, f) \le D_i$

Example 35

 $T_1 = (4, 1.0), T_2 = (5, 1.8), T_3 = (20, 1.0), T_4 = (20, 2.0)$ Then $f \in \mathbb{N}$ satisfies 1.–3. iff f = 2.

With f = 2 is schedulable:

Frame Based Scheduling – Job Slices

Sometimes a system cannot meet all three frame size constraints simultaneously (and even if it meets the constraints, no non-preemptive schedule is feasible)

Frame Based Scheduling – Job Slices

- Sometimes a system cannot meet all three frame size constraints simultaneously (and even if it meets the constraints, no non-preemptive schedule is feasible)
- Can be solved by partitioning a job with large execution time into slices with shorter execution times

This, in effect, allows preemption of the large job

Frame Based Scheduling – Job Slices

- Sometimes a system cannot meet all three frame size constraints simultaneously (and even if it meets the constraints, no non-preemptive schedule is feasible)
- Can be solved by partitioning a job with large execution time into slices with shorter execution times This, in effect, allows preemption of the large job
- Consider $T_1 = (4, 1), T_2 = (5, 2, 7), T_3 = (20, 5)$
- Cannot satisfy constraints: $1. \Rightarrow f \ge 5$ but $3. \Rightarrow f \le 4$
- Solve by splitting T_3 into $T_{3,1} = (20, 1), T_{3,2} = (20, 3)$, and $T_{3,3} = (20, 1)$

(Other splits exist)

Result can be scheduled with f = 4

To construct a schedule, we have to make three kinds of design decisions (that cannot be taken independently):

- Choose a frame size based on constraints
- Partition jobs into slices
- Place slices into frames

There are efficient algorithms for solving these problems based e.g. on a reduction to the network flow problem.

Scheduling Aperiodic Jobs

So far, aperiodic jobs scheduled in the background after all jobs with hard deadlines

This may unnecessarily delay aperiodic jobs

Scheduling Aperiodic Jobs

So far, aperiodic jobs scheduled in the background after all jobs with hard deadlines

This may unnecessarily delay aperiodic jobs

Note: There is no advantage in completing periodic jobs early Ideally, finish periodic jobs by their respective deadlines.

Scheduling Aperiodic Jobs

So far, aperiodic jobs scheduled in the background after all jobs with hard deadlines

This may unnecessarily delay aperiodic jobs

Note: There is no advantage in completing periodic jobs early Ideally, finish periodic jobs by their respective deadlines.

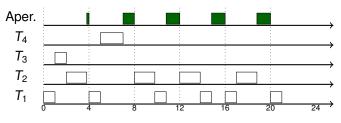

Slack Stealing:

- Slack time in a frame = the time left in the frame after all (remaining) slices execute
- Schedule aperiodic jobs ahead of periodic in the slack time of periodic jobs
 - The cyclic executive keeps track of the slack time left in each frame as the aperiodic jobs execute, preempts them with periodic jobs when there is no more slack
 - As long as there is slack remaining in a frame and the aperiodic jobs queue is non-empty, the executive executes aperiodic jobs, otherwise executes periodic
- Reduces resp. time for aper. jobs, but requires accurate timers

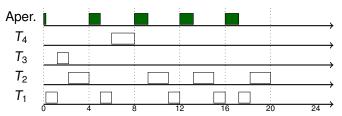

Example

Assume that the aperiodic queue is never empty.

Aperiodic at the ends of frames:

Slack stealing:

Frame Based Scheduling – Sporadic Jobs

Let us allow sporadic jobs

i.e. hard real-time jobs whose release and exec. times are not known a priori

Frame Based Scheduling – Sporadic Jobs

Let us allow sporadic jobs

i.e. hard real-time jobs whose release and exec. times are not known a priori

The scheduler determines whether to accept a sporadic job when it arrives (and its parameters become known)

Perform acceptance test to check whether the new sporadic job can be feasibly scheduled with all the jobs (periodic and sporadic) in the system at that time

Acceptance check done at the beginning of the next frame; has to keep execution times of the parts of sporadic jobs that have already executed

- If there is sufficient slack time in the frames before the new job's deadline, the new sporadic job is accepted; otherwise, rejected
- Among themselves, sporadic jobs scheduled according to EDF This is optimal for sporadic jobs

Frame Based Scheduling – Sporadic Jobs

Let us allow sporadic jobs

i.e. hard real-time jobs whose release and exec. times are not known a priori

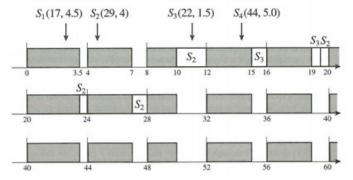

The scheduler determines whether to accept a sporadic job when it arrives (and its parameters become known)

Perform acceptance test to check whether the new sporadic job can be feasibly scheduled with all the jobs (periodic and sporadic) in the system at that time

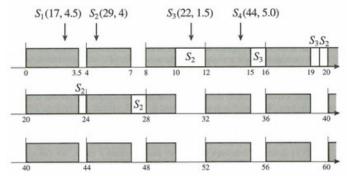

Acceptance check done at the beginning of the next frame; has to keep execution times of the parts of sporadic jobs that have already executed

- If there is sufficient slack time in the frames before the new job's deadline, the new sporadic job is accepted; otherwise, rejected
- Among themselves, sporadic jobs scheduled according to EDF This is optimal for sporadic jobs

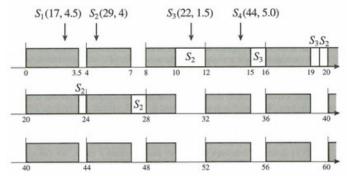

Note: rejection is often better than missing deadline e.g. a robotic arm taking defective parts off a conveyor belt: if the arm cannot meet deadline, the belt may be slowed down or stopped

S₁(17, 4.5) released at 3 with abs. deadline 17 and execution time 4.5; acceptance test at 4; must be scheduled in frames 2, 3, 4; total slack in these frames is 4, i.e. rejected

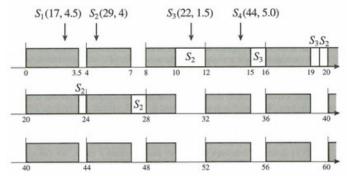

- S₁(17, 4.5) released at 3 with abs. deadline 17 and execution time 4.5; acceptance test at 4; must be scheduled in frames 2, 3, 4; total slack in these frames is 4, i.e. rejected
- S₂(29, 4) released at 5 with abs. deadline 29 and exec. time 4; acc. test at 8; total slack in frames 3-7 is 5.5, i.e. accepted

- S₁(17, 4.5) released at 3 with abs. deadline 17 and execution time 4.5; acceptance test at 4; must be scheduled in frames 2, 3, 4; total slack in these frames is 4, i.e. rejected
- S₂(29,4) released at 5 with abs. deadline 29 and exec. time 4; acc. test at 8; total slack in frames 3-7 is 5.5, i.e. accepted
- S₃(22, 1.5) released at 11 with abs. deadline 22 and exec. time 1.5; acc. test at 12;

2 units of slack in frames 4, 5 as S_3 will be executed *ahead of the remaining parts of* S_2 by EDF – check whether there will be enough slack for the remaining parts of S_2 , accepted

- S₁(17, 4.5) released at 3 with abs. deadline 17 and execution time 4.5; acceptance test at 4; must be scheduled in frames 2, 3, 4; total slack in these frames is 4, i.e. rejected
- S₂(29,4) released at 5 with abs. deadline 29 and exec. time 4; acc. test at 8; total slack in frames 3-7 is 5.5, i.e. accepted
- S₃(22, 1.5) released at 11 with abs. deadline 22 and exec. time 1.5; acc. test at 12;

2 units of slack in frames 4, 5 as S_3 will be executed *ahead of the remaining parts of* S_2 by EDF – check whether there will be enough slack for the remaining parts of S_2 , accepted

S₄(44, 5.0) is rejected (only 4.5 slack left)

Handling Overruns

Overruns may happen due to failures

e.g. unexpectedly large data over which the system operates, hardware failures, etc.

Overruns may happen due to failures

e.g. unexpectedly large data over which the system operates, hardware failures, etc.

Ways to handle overruns:

- Abort the overrun job at the beginning of the next frame; log the failure; recover later
 e.g. control law computation of a robust digital controller
- Preempt the overrun job and finish it as an aperiodic job use this when aborting job would cause "costly" inconsistencies
- Let the overrun job finish start of the next frame and the execution jobs scheduled for this frame are delayed

This may cause other jobs to be delayed depends on application

Clock-drive Scheduling: Conclusions

Advantages:

- Conceptual simplicity
 - Complex dependencies, communication delays, and resource contention among jobs can be considered when constructing the static schedule
 - Entire schedule in a static table
 - No concurrency control or synchronization needed
- Easy to validate, test and certify

Advantages:

- Conceptual simplicity
 - Complex dependencies, communication delays, and resource contention among jobs can be considered when constructing the static schedule
 - Entire schedule in a static table
 - No concurrency control or synchronization needed
- Easy to validate, test and certify

Disadvantages:

- Inflexible
 - If any parameter changes, the schedule must be usually recomputed
 Best suited for systems which are rarely modified (e.g. controllers)
 - Parameters of the jobs must be fixed
 As opposed to most priority-driven schedulers

Real-Time Programming & RTOS

Concurrent and real-time programming tools

Concurrent Programming

Concurrency in real-time systems

- typical architecture of embedded real-time system:
 - several input units
 - computation
 - output units
 - data logging/storing
- i.e., handling several concurrent activities
- concurrency occurs naturally in real-time systems

Support for concurrency in programming languages (Java, Ada, ...) advantages: readability, OS independence, checking of interactions by compiler, embedded computer may not have an OS

Support by libraries and the operating system (C/C++ with POSIX) advantages: multi-language composition, language's model of concurrency may be difficult to implement on top of OS, OS API stadards imply portability

Processes and Threads

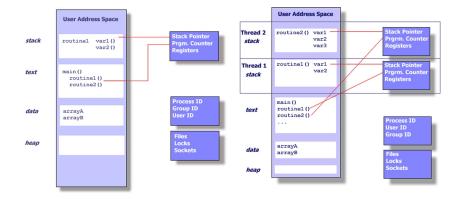

Process

- running instance of a program,
- executes its own virtual machine to avoid interference from other processes,
- contains information about program resources and execution state, e.g.:
 - environment, working directory, ...
 - program instructions,
 - registers, heap, stack,
 - file descriptors,
 - signal actions, inter-process communication tools (pipes, message boxes, etc.)

Thread

- exists within a process, uses process resources ,
- can be scheduled by OS and run as an independent entity,
- keeps its own: execution stack, local data, etc.
- share global data and resources with other threads of the same process

Processes and threads in UNIX

Communication and Synchronization

Communication

- passing of information from one process (thread) to another
- typical methods: shared variables, message passing

Synchronization

 satisfaction of constraints on the interleaving of actions of processes

e.g., action of one process has to occur after an action of another one

typical methods: semaphores, monitors

Communication and synchronization are linked:

- communication requires synchronization
- synchronization corresponds to communication without content

Concurrent Programming is Complicated

Multi-threaded applications with **shared data** may have numerous flaws.

Race condition

Two or more threads try to access the same shared data, the result depends on the exact order in which their instructions are executed

Deadlock

occurs when two or more threads wait for each other, forming a cycle and preventing all of them from making any forward progress

Starvation

an idefinite delay or permanent blocking of one or more runnable threads in a multithreaded application

Livelock

occurs when threads are scheduled but are not making forward progress because they are continuously reacting to each other's state changes

Usually difficult to find bugs and verify correctness.

time-aware systems make explicit references to the time frame of the enclosing environment

e.g., a bank safe's door are to be locked from midnight to nine o'clock

- the "real-time" of the environment must be available
- reactive systems are typically concerned with relative times

an output has to be produced within 50 ms of an associated input

- must be able to measure intervals
- usually must synchronize with environment: input sampling and output signalling must be done very regularly with controlled variability

The Concept of Time

Real-time systems must have a concept of time – but what is time?

- Measure of a time interval
 - Units?
 - seconds, milliseconds, cpu cycles, system "ticks"
 - Granularity, accuracy, stability of the clock source
 - Is "one second" a well defined measure?
 "A second is the duration of 9,192,631,770 periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the caesium-133 atom."
 - ... temperature dependencies and relativistic effects
 - Skew and divergence among multiple clocks Distributed systems and clock synchronization
- Measuring time
 - external source (GPS, NTP, etc.)
 - internal hardware clocks that count the number of oscillations that occur in a quartz crystal

For RT programming, it is desirable to have:

- access to clocks and a representation of time
- delays
- timeouts
- (deadline specification and real-time scheduling)

Access to Clock and Representation of Time

- requires a hardware clock that can be read like a regular external device
- mostly offered by an OS service, if direct interfacing to the hardware is not allowed

Example of time representation: (POSIX high resolution clock, counting seconds and nanoseconds since 1970 with known resolution)

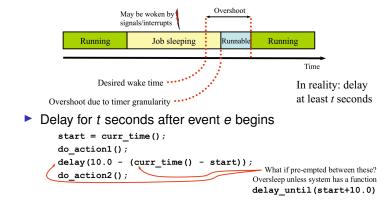

```
const struct timespec * tp );
```

Time is often kept by incrementing an integer variable, need to take case of overflows (i.e., jumps to the past).

Delays

In addition to having access to a clock, need ability to

- Delay execution until an arbitrary calendar time What about daylight saving time changes? Problems with leap seconds.
- Delay execution for a relative period of time
 - Delay for t seconds

The overshoots accumulate = the drift!

Timers

- Set an alarm clock, do some work, and then wait for whatever time is left before the alarm rings
- This is done with timers
- Thread is told to wait until the next ring
- Two types of timers
 - one-shot

After a specified interval call an associated function.

- periodic (also called auto-reload timer in freeRTOS)
 Call the associated function repeatedly, always after the specified interval.
- Even with periodic timers, the overshoots occur but they do not accumulate (local drift)

Timeouts

Synchronous blocking operations can include timeouts

- Synchronization primitives Semaphores, locks, etc.
 - ... timeout usually generates an error/exception
- Networking and other I/O calls
 - E.g. select() in POSIX

Monitors readiness of multiple file descriptors, is ready when the corresponding operation with the file desc is possible without blocking. Has a timeout argument that specifies the minimum interval that select() should block waiting for a file descriptor to become ready.

May also provide an asynchronous timeout signal

 Detect time overruns during execution of periodic and sporadic tasks

Deadline specification and real-time scheduling

Clock driven scheduling trivial to implement via cyclic executive.

Other scheduling algorithms need OS and/or language support:

- System calls create, destroy, suspend and resume tasks.
- Implement tasks as either threads or processes. Threads usually more beneficial than processes (with separate address space and memory protection):
 - Processes not always supported by the hardware
 - Processes have longer context switch time
 - Threads can communicate using shared data (fast and more predictable)
- Scheduling support:
 - Preemptive scheduler with multiple priority levels
 - Support for aperiodic tasks (at least background scheduling)
 - Support for sporadic tasks with acceptance tests, etc.

- In theory, a system comprises a set of (abstract) tasks, each task is a series of jobs
 - tasks are typed, have various parameters, react to events, etc.
 - Acceptance test performed before admitting new tasks
- In practice, a thread (or a process) is the basic unit of work handled by the scheduler
 - Threads are the instantiation of tasks that have been admitted to the system

How to map tasks to threads?

Periodic Tasks

Real-time tasks defined to execute periodically $T = (\phi, p, e, D)$

It is clearly inefficient if the thread is created and destroyed repeatedly every period

- Some op. systems (funkOS) and programming languages (Real-time Java & Ada) support *periodic threads*
 - the kernel (or VM) reinitializes such a thread and puts it to sleep when the thread completes
 - The kernel releases the thread at the beginning of the next period
 - This provides clean abstraction but needs support from OS
- Thread instantiated once, performs job, sleeps until next period, repeats
 - Lower overhead, but relies on programmer to handle timing
 - Hard to avoid timing drift due to sleep overuns (see the discussion of delays earlier in this lecture)
 - Most common approach

Sporadic and Aperiodic Tasks

Events trigger sporadic and aperiodic tasks

- Might be extenal (hardware) interrupts
- Might be signalled by another task

Usual implementation:

- OS executes periodic server thread (background server, deferrable server, etc.)
- OS maintains a "server queue" = a list of pointers which give starting addresses of functions to be executed by the server
- Upon the occurrence of an event that releases an aperiodic or sporadic job, the event handler (usually an interrupt routine) inserts a pointer to the corresponding function to the list

Real-Time Programming & RTOS

Real-Time Operating systems

Operating Systems – What You Should Know ...

An operating system is a collection of software that manages computer hardware resources and provides common services for computer programs.

Basic components multi-purpose OS:

- Program execution & process management processes (threads), IPC, scheduling, ...
- Memory management segmentation, paging, protection ...
- Storage & other I/O management files systems, device drivers, ...
- Network management network drivers, protocols, ...
- Security

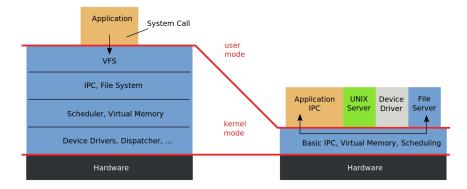

user IDs, privileges, ...

 User interface shell, GUI, ...

Operating Systems – What You Should Know ...

Microkernel based Operating System

Implementing Real-Time Systems

- Key fact from scheduler theory: need predictable behavior
 - Raw performance less critical than consistent and predictable performance; hence focus on scheduling algorithms, schedulability tests
 - Don't want to fairly share resources be unfair to ensure deadlines met

Need to run on a wide range of – often custom – hardware

- Often resource constrained: limited memory, CPU, power consumption, size, weight, budget
- Closed set of applications
 (Do we need a cardiac pacemaker playing music?)
- Strong reliability requirements may be safety critical
- How to upgrade software in a car engine?

Implications on Operating Systems

- General purpose operating systems not well suited for real-time
 - Assume plentiful resources, fairly shared amongst untrusted users
 - Serve multiple purposes
 - Exactly opposite of an RTOS!
- Instead want an operating system that is:
 - Small and light on resources
 - Predictable
 - Customisable, modular and extensible
 - Reliable

... and that can be *demonstrated* or *proven* to be so

Implications on Operating Systems

- Real-time operating systems typically either cyclic executive or microkernel designs, rather than a traditional monolithic kernel
 - Limited and well defined functionality
 - Easier to demonstrate correctness
 - Easier to customise
- Provide rich support for concurrency & real-time control
- Expose low-level system details to the applications control of scheduling, interaction with hardware devices, ...

Cyclic Executive without Interrupts

The simplest real-time systems use a "nanokernel" design

- Provides a minimal time service: scheduled clock pulse with a fixed period
- No tasking, virtual memory/memory protection etc.
- Allows implementation of a static cyclic schedule, provided:
 - Tasks can be scheduled in a frame-based manner
 - All interactions with hardware to be done on a polled basis
- Operating system becomes a single task cyclic executive

```
setup timer
c = 0;
while (1) {
    suspend until timer expires
    c++;
    do tasks due every cycle
    if (((c+0) % 2) == 0) do tasks due every 2nd cycle
    if (((c+1) % 3) == 0) {
        do tasks due every 3rd cycle, with phase 1
    }
    ...
```

- Cyclic executive widely used in low-end embedded devices
 - 8 bit processors with kilobytes of memory
 - Often programmed in (something like) C via cross-compiler, or assembler
 - Simple hardware interactions
 - Fixed, simple, and static task set to execute
 - Clock driven scheduler
- But many real-time embedded systems are more complex, need a sophisticated operating system with priority scheduling
- Common approach: a microkernel with priority scheduler Configurable and robust, since architected around interactions between cooperating system servers, rather than a monolithic kernel with ad-hoc interactions

A microkernel RTOS typically provides:

- Timing services, interrupt handling, support for hardware interaction
- Task management, scheduling
- Messaging, signals
- Synchronization and locking
- Memory management (and sometimes also protection)

- RTOS for embedded devices (ported to many microcontrollers from more than 20 manufacturers)
- Distributed under GPL
- Written in C, kernel consists of 3+1 C source files (approx. 9000 lines of code including comments)
- Largely configurable

Example RTOS: FreeRTOS

- The OS is (more or less) a library of object modules; the application and OS modules are linked together in the resulting executable image
- Prioritized scheduling of tasks
 - tasks correspond to threads (share the same address space; have their own execution stacks)
 - highest priority executes; same priority \Rightarrow round robin
 - ► implicit idle task executing when no other task executes ⇒ may be assigned functionality of a background server
- Synchronization using semaphores
- Communication using message queues
- Memory management
 - no memory protection in basic version (can be extended)
 - various implementations of memory management memory can/cannot be freed after allocation, best fit vs combination of adjacent memory block into a single one

That's (almost) all

Tiny memory requirements: e.g. IAR STR71x ARM7 port, full optimisation, minimum configuration, four priorities \Rightarrow

- size of the scheduler = 236 bytes
- each queue adds 76 bytes + storage area
- each task 64 bytes + the stack size
